WORLD STREAMER MANUAL 1.2

Introduction to World Streamer

World Streamer is a memory ASYNC streaming system. By using it you are able to stream your whole game from a disc in any axis and space. You can create endless space games, 2D platformers, 3rd person, open worlds, mobile apps, architectural presentations, single, multiplayer, or any kind of game you want without loading screens during player movement. You are also able to create endless looped worlds or planet imitation.

All scene assets will be stored on the disk as scene files and they will be loaded only when they are close enough or when they meet the required conditions. This solution reduces CPU, RAM, VRAM, GPU usage, and performance in your game will be much, much better and your application will load much faster. With streaming you will reduce the object count in your scene and you can create very detailed and large scenes without the performance drop. World streamer gives you the ability to create your scenes, as big as you want, without any limits.

"Floating Point Fix System" removes restrictions and errors caused by huge coordinates in the engine. With "Local Area Updater" you can work on a small, local area without loading the entire world. Easily add these changes to the world by clicking just 2 buttons. This means you will not have Unity Editor slow down, because of loading the entire world into the editor scene.

You can also separate your world into layers such as Lighting, AI, Geometry far in the distance, Geometry Near, Trees, etc. Ring streaming gives you the ability to replace objects in the distance with lower Level Of Detail models. You are able to replace detailed terrain with lower poly mesh when it's far in the distance. Collider streaming gives you the ability to load buildings, rooms, caves, interiors, etc, when you are close enough to them and when you enter/hit the collider or portal which triggers them.

World Streamer is a perfect solution for teams that work on the same project at the same time, even in the same area. Team members are able to work on separate areas of the world and then save their changes into the world when ready using Local Area Updater. Team members can work in the same area at the same time as well, by working on different layers.

We have provided an extensive manual as per the community's request to thoroughly explain everything, but once you understand the basics you will be able to prepare your game for streaming with only a few buttons and in few minutes or even seconds.

Features:

- Floating point error fix system.
- Looped world system.
- Multiplayer support.
- Multi scene editing support.
- Unity 5.3+ support but it also works on older unity versions.
- Stream in multiple independent layers.
- Support for multiple developers working in one area.
- Removes world size restrictions.
- Ability to work in Unity huge or extremely detailed scenes without slowing down the editor.
- Support for massive worlds.
- Easy automatic processes will save your development time.
- In few clicks you can stream endless world.
- Work in any axis and space: 2d, 3d, vertical, horizontal.
- Reduce RAM,CPU,GPU,VRAM usage of your game.
- Reduce number of objects in your scene.
- Compatible with unity5 speedtree or any tree system.
- Load your world in background (async loading).
- Compatible with Amplify, Granite and any other texture streaming system.
- Loading screen system included.
- LOD system for terrains.
- Additional terrain culling system, it reduce 10-90% of terrain cpu/gpu usage (Unity 5.3+)
- Ring streaming can replace object by objects in the distance with lower Level of Detail models. For example high quality terrain can be changed to low poly mesh when it's far in the distance.
- Collide streaming option, stream interior areas when you walk through doors or trigger a collider.
- Streamed scenes could stream scenes (matrioshka construction).
- Webplayer support.
- Innovative local area updater allows Unity Editor to load only a specific area/layer of massive world.
- Compatible with Terrain Stitcher and Multiple Terrain Brush,
- Fully commented opensource code that will help you to work with and expand World Streamer!
- Batching support,
- compatible with:

World Creator https://www.assetstore.unity3d.com/en/#!/content/55073 Gaia https://www.assetstore.unity3d.com/en/#!/content/42618 Terrain Composer https://www.assetstore.unity3d.com/en/#!/content/65563 RTP https://www.assetstore.unity3d.com/en/#!/content/51881 uConstruct https://www.assetstore.unity3d.com/en/#!/content/51881 Trees Manager System https://www.assetstore.unity3d.com/en/#!/content/43129 Gena uNature Curved World https://www.assetstore.unity3d.com/en/#!/content/26165

1. Idea of streaming - very important

The idea is pretty simple. Your huge world will be split into smaller parts by our tools. These parts are elements on a virtual grid. World Streamer will load these virtual grid elements when an "object" (player or other object) is close enough to the grid element. You can also load grid elements when the player hits a collider (collider streaming).

In most cases, we recommend to use the player as this "object", not the camera. For RTS games or 2D platform games, setting the camera as the followed object is a better solution. Because we save everything as a scene, you can still use lightmaps, navmesh, GI, batching, baked colliders and everything that you can save in a scene, but not Occlusion Culling. Unity doesn't support asynchronous Occlusion Culling loading yet. You could use a custom culling solution or cull objects by removing them from memory and the scene, when they are far enough away or behind wall. For an example of objects culled by streaming, you could load small stones only when you are really close to them or use collider streaming to load building interior only when you are on the correct floor or close to the entrance.

With World Streamer you are able to replace grid elements with grid elements from another layer depending on distance. You can use this as a LOD solution for objects that Unity's LOD system doesn't support or for objects where LODO is really heavy - like Unity terrain objects. You can replace your Unity Terrain with a simple mesh when it's at a far distance, this will greatly reduce culling and refresh operations (CPU) and memory usage. Unity terrains can be very heavy so this can save hundreds MB of RAM. More info about working with Unity terrains, objects, etc are found further in this manual.

World Streamer contains has the ability to stream in layers, which means that you can put different objects on different layers. For example, you could have a layer for terrain, one for trees, one for rocks, and one for sounds effects. Each layer will load objects independently.

A good way to use layers is to group objects together by size and load only small objects near the player, but have larger objects loaded in the distance. For example, buildings which need to be seen in the distance can be on their own layer, medium sized details like boxes and lanterns could be added to a 'Medium' distance layer, while smaller details like papers, dirt, and small stones are added to their own layer as well. For the terrain, a layer containing a detailed terrain can be used when the player is near and when the player is far away from the terrain, a separate layer with a low poly mesh of the terrain can be shown.

If you put all these things on different layers, you could setup how far each object (layer) will be visible and stay in RAM, VRAM, CPU, GPU. This is a dynamic setting so you can manage this during gameplay for the player. Each layer and its range of streaming can be configured differently. Even each axis direction X,Y,Z can have different settings for range of streaming. Layers also can be used to separate lights, particles, and other effects from 3D content. This allows multiple team members to work on the same map and region at the same time.

After you have split your world into parts you are always able to recreate one big, un-split scene by using the Local Area Updater tool. This means that you can always undo the fragmentation of your world and merge any changes into a whole scene again.

The basic idea is to split your world into many virtual grid elements in many different layers and then load them asynchronously without any CPU impact to save a lot of performance in CPU, GPU, RAM, VRAM.

REMEMBER: The real power of World Streamer is at build. During the build process Unity Editor bakes many things like collisions and batching. If you use World Streamer in the editor, these operations must be done at runtime and sometimes they are not asynchronous or simply put they are heavy. You could reduce these spikes by temporarily turning off static batching, etc, but only while in the editor. You will lose performance (drawcalls will grow up) in the editor. However, at build everything will be fine.

2. World System project requirements

• You must add the following tags to the project: SceneStreamer, WorldMover, ColliderStreamerManager.

✓ SceneStreamer

The SceneStreamer tag must be assigned to any GameObject that uses a Streamer.cs script. The _Streamer_Major and _Streamer_Minor prefabs must have the SceneStreamer tag.

✓ WorldMover

The WorldMover tag must be assigned to any GameObject that uses a WorldMover.cs Script. The _World_Mover prefab must have the WorldMover tag.

✓ ColliderStreamerManager

The ColliderStreamerManager tag must be assigned to any GameObject that uses a ColliderStreamerManager.cs script.

The _Collider_Streamer_Manager prefab must have the ColliderStreamerManager tag.

	Max Parallel Scene Loading	1	
	Scene Load Wait Frames	1	
	Player	None (Transform)	0
	Terrain Neighbours	None (Terrain Neighbours)	0

These streamer system prefabs must all have tags! If you do not add them, World Streamer cannot load anything at build or even in the editor. You will get many errors if you have not added the required tags. *Always check tags in new project!*

- To start you need "Work" scene where you hold all models that will be streamed from the disc. This scene
 or scenes will be used to split your world into virtual grid elements, multiple layers. If you have unity 5.3+,
 this scene could be used once because whole work could be continued on split scenes. Of course you could
 recreate "Work" scene again from split scenes by Local Scene Updater Tool.
- All models and objects in "Work" scene should be unpacked from catalogues in hierarchy. All info about how streamer holds, recognizes your models/objects, terrains you will find in manual in proper section. Don't worry there will be no mess after virtual grid creation.
- **To stream you need "Gameplay"** scene where you hold: player, direction light, camera, your UI, everything else (world) could be loaded from the disc. You will put streamer prefabs there and they will load everything that you want. Please prepare it before you start. You will fill streamer prefabs when your world will be split in many parts.

3. Quick Start - Test Scene

1. You must configure the proper Tags to use the demo scenes please check <u>"2 World Streamer project</u> requirements." section.

Advanced scenes use ring streaming (terrains), collider streaming and looped unity terrains, they are more spectacular. In our example we will show Advanced Scene.

3. Click on each streamer object in your hierarchy and click "add to build settings" button. We must have all grid elements (scenes) in our build settings. Without this we could not load them.

4. If you have opened simple scene instead of advanced you can skip this step.
As we also stream models by collider streaming in our Advanced Game scene, we have to add our scene with building interior to build settings so: "WorldStreamer" catalog → "SplitScenes" → "ColliderScenes" → "Prefabs" → click on "Medium_Collider_Streaming_Floor_0_stream" prefab.

Then you have to click add to build settings button. Do the same operations for "Floor_1", "Floor_2".

Of course there is easier, more automatic and faster way to do this but now we want to show some basic information about how system works.

5. Hit play and run around, take a look how everything is streamed.

4. World Streamer details and settings

Streaming solution consists of:

- Scene splitter. This tool is used to create virtual grids and layers from your scene objects. Scene splitter also generates scenes from virtual grid elements. During scene generating process scene splitter create also scene collections which we called "SC+Prefix". Scene collection is created for each layer.
- Scene collections. This prefabs which we call "SC+Prefix" hold information about scenes, grid element size, world size and much more details that are useful for streaming process. As we mentioned they are formed and refreshed by scene splitter or local area updater tool, during scene generation process.
- Scene objects. They are connected to scene collections "SC+Prefix", they are formed and refreshed by scene splitter or local area updater tool during scene generation process.
- Streamer prefabs (Major, Minor). They hold and use scene collections "SC+Prefix" in your "Gameplay" scene and they stream content according to options that you set. First streamer at your scene should be Major, it should be used for:
 - terrains
 - big objects (if you don't stream terrains)
 - all objects (if you use only one layer)

All other streamer should be minor.

- **Collider streamers.** They holds scene which will be loaded after chosen object hit his collider.
- **Collider_Stream_Manager.** Is a prefab that give you ability to stream objects by Collider streamers. This object also gives you ability to stream scenes from colliders which are hidden in grid elements. Yes, you could create matrioshka streaming construction (streamed scene that stream scenes).
- Local area updater. This tool gives you ability to merge scenes, load only local area, refresh/modify/remove parts of the already split world. It gives developers the ability to work on the same area, at the same time.
- **Streamer GUI.** Our loading screen, teleport, respawn, position debug, UI which you could modify and adapt to your game construction.
- World_Mover. This object is used in floating point fix system to restart world position and it also holds connection between real and local restarted world position. This connection is useful for spawned objects or server communication.
- Player teleport. It's an object that holds respawn/teleport point position. This could be dynamic object.
- **Object to move**. This script holds relation between non-streamed object and player, while floating point fix system resets the position.
- **TerrainNeighbour.** This script blend edges between neighboring terrains. It's useful because terrains must have synchronized LODs, otherwise terrains borders will have small holes.
- TerrainCullingSystem. This script gives additional performance boost to terrain rendering and streaming.

4.1 Scene splitter

This tool is used to split your world objects into virtual grids and prepare them into streaming. As objects we mean: models, objects, lights, particles, terrains. Every grid element "grid eye" will be a "pack" of data that World Streamer load into memory as one object.

We always advice you to open "scene splitter" at empty scene that we will call "Work" scene. You should copy into it whole content that you want to stream. Directional lights, player, UI should be at your "Gameplay" scene, so remove them from this "Work" scene or hide during splitting process. If you will properly set your layers, this objects could stay here.

To open "Scene Splitter" window click at "World Streamer"→"Scene Splitter"

File Edit Ass	ets GameObject Component	Mobile Input Asset Store Tools	World Streamer Wi	ndow Help

Splitting tiles				
	Split scene in	ito virtual Grid		
	Clear So	cene Split		
Scene Generation				
	Generate Scenes	from virtual Grid		
	Generates Scenes	from colliders only		

Add layer button creates a group/layer of objects. Layer separates specified objects from the rest of objects, this layer/group will be streamed independently from others. As an example of layers/groups we could use: Terrains, Small models, Big models, Medium models, Far low poly Terrains, Lights, Particles, FX. Please also read about layer order in this section, to get very important info about how "Scene Splitter" recognize your objects. You must have at least one layer to split your scene.

- Split X, Split Y, Split Z buttons give you ability to chose what Axis will be used during virtual grid generation. If you create space game you will <u>probably</u> check X,Y,Z. If you create RTS of RPG, Car game you <u>probably</u> will check X and Z because height is not so important. For unity terrain you should check only X and Z. If you want to unload terrains when player is to high over terrains you could check Y too.
- X size, Y size, Z size values are responsible for size of one virtual grid element "eye". You are creating virtual grid which is based on your checked Split X, Split Y, Split Z axis and their size which you chose right here. Grid element size should be estimated by you. You could easily change it and test different values. They shouldn't be too big because you will load too much objects at once. They shouldn't be too small because you will have huge amount of scenes, which are probably unnecessary. You have to confront that also to object size, if your big building is 200x200 units you shouldn't stream it in 20x 20 grid element size, but you could stream a group of these buildings in 1000x1000 virtual grid element. Of course if they are not too heavy as one grid element.

For **unity terrain** "X size" and "Z size" should/**MUST** be the same size as terrain length and width. More about unity terrains you will find in <u>"5. Terrain streaming."</u> exactly in <u>"5.2 Scene split and virtual grid setup."</u> section.

You could **visualize your virtual grid element size** by using our gizmo. After you click "Split Scene" or "S" button, when you click at virtual grid element that system just created, you will see its boundaries. **Before this** you have to fill all info about virtual grid and layer to create first split.

• **GameObject Prefix** is really important value. While splitting system is searching for objects, because it wants to put them into correct layers, it's checking each object's name. If you will leavegame object prefix as empty, system will put all objects at the scene into one layer.

If for **Example.1** you want to put your unity terrains into layer "Terrain_Lod0", fill game object prefix for example by "Terrain". Add "Terrain" word at beginning of each terrain object at the scene.

	Scene Splitter

	Generate Scenes from virtual Grid	
	Generates Scenes from colliders only	

You can rename your objects in prefabs, this will save your time, because this operation should change
names also at your scene. We know that it could take some time, but if you want to automatically assign
objects to layers and don't care about when they should be streamed, save a lot of performance, you have
to prepare your objects first and declare what they are.

Ez Files Rename - easy and fast tool which will rename your objects at project and hierarchy. It's useful to rename your assets to layer and split purposes. <u>https://www.assetstore.unity3d.com/en/#!/content/31082</u>

Scene Prefix (layer name), in this place you choose name of your virtual grid and scenes (virtual grid elements) for each layer. For example you could leave it the same as "GameObject Prefix" so "Small" and "Terrain_Lod0" or add info about scene/world that you are currently working on, like: World_A_Small_Models, World_A_Terrain_Lod0. After you click split, virtual grid elements will appear and they will hold "Scene Prefix" in name + number of row and column that they have in virtual grid. Look at images below.

				Split scene	e into virtual Grid
				Clear	Scene Split

• Split Scene into virtual Grid when you hit this button, system will check all objects in the scene and put them in correct virtual grid element and layer. This will be done for all layers and objects. In first step scene splitter will check all objects names, if they are contain correct/specified prefix, it will put this objects to layer which contain this prefix. In next step system will check objects position (their pivot!) in layer and will move them to correct virtual grid element. Look at image above. Reason why your objects should be unpacked from mother/parent catalogues at your "Work" scene hierarchy is: If you put your object into other object as child, from this moment his pivot position will be taken from his parent/mother object. This could change his position in virtual grid. It depends how big difference is between parent/mother and child objects pivots positions. To check your object pivot position click at your object in scene hierarchy and you need this option to be enabled:

File Edit Assets GameObject	Component World Streamer	Mobile Input	Window	Help			
🕲 💠 S 🗷 🔟 🛛	■ Pivot 📽 Local						
🛱 Asset Store 🛛 🗲 Game	# Scene						
	#				$\mathbf{\overset{1}{\succ}}$	EN 👻	2 -

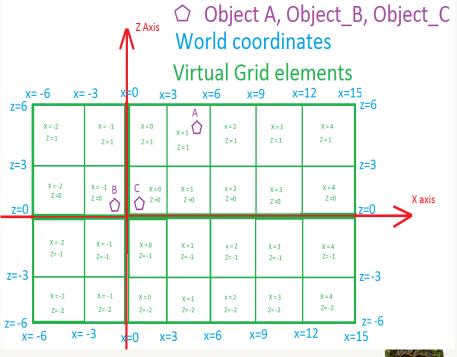

Example:

We have Layer called "Models", it has Game object prefix "Object", virtual grid size is X=3 Y=3 Z=3. So we have virtual grid with grid elements that are 3x3x3 units each.

At scene there are 3 objects: Object_A with position x=5, y=5, z=5, Object_B with position x=-1 y=,1, z=1, Object_C with position x=0, y=0, z= 0,

Take a look at image which will help to understand example.

Important: Virtual grid elements starts from 0, 0, 0.

After click "Split scene into virtual Grid " button system will move: Object_A to layer "Models" and to virtual grid element with name Models_x1_y1_z1, Object_B to layer "Models" and to virtual grid element with name Models_x-1,y0_z0, Object_C into layer "Models" and to virtual grid element with name Models_x0_y0_z0 Part of name "x-1,y0,z0" in virtual grid element is number of column and row in virtual grid.

- **Clear Scene Split**, when you hit this button you will undo whole split operation. All objects will be unpacked from virtual grid elements and virtual grid will disappear.
- Generate Scenes from Virtual Grid when you are sure about virtual grids and their elements and you hit this button, system will prepare/generate scenes from virtual grids elements for each layer. It will also generate scene collection "SC+Prefix" prefab in scenes catalog. Scene collection "SC+Prefix" prefab holds whole information about layer and scenes/virtual grid elements connected to this layer. In short we could say, when you click "generate scenes" button, system will change virtual grid elements into scenes with information about layer that they belong to.
- Scene create folder is a place at your project where your scenes and Scene Collections "SC+Prefix" prefabs will be stored after you click "Generate Scenes" button.

• Buttons S,G,C,X

- S you are able to split/generate virtual grid elements only for this layer separately from others
- G you are able to generate scenes from virtual grid elements only from this layer separately from others
- C you are able to unsplit/remove virtual grid elements only for this layer separately from others

X - you are able to delete this layer separately from the others

- Layer order is really important, but only when you create a layer with empty "GameObject prefix". If you put layer with empty "GameObject prefix" as first, system will move all objects at the scene and create virtual grid elements with them. Other layers will have empty list to check and as a result they will be empty
- **Gizmo color** when you click on virtual grids, scene splitter will show you their boundaries in color that you specified. This gizmo color will be also useful to visualize streaming range for each layer in "Gameplay" scene.

- Scene Collection is a place where you connect streaming system with your scene collections "SC+Prefix" prefabs, which holds information about virtual grid elements(scenes). Simply drag and drop scene collection "SC+Prefix" prefab into this window. Scene collection prefab is in catalog with generated scenes, which it belongs to, so WorldStreamer→SplitScenes→Layer name
- Loading range is an integer value in each axis that precise virtual grid elements radius that you want hold at RAM memory at once. Loading range could be different for every axis in your world. When you click on Streamer object you could see gizmo at your screen with current loading range area, look at screen above.

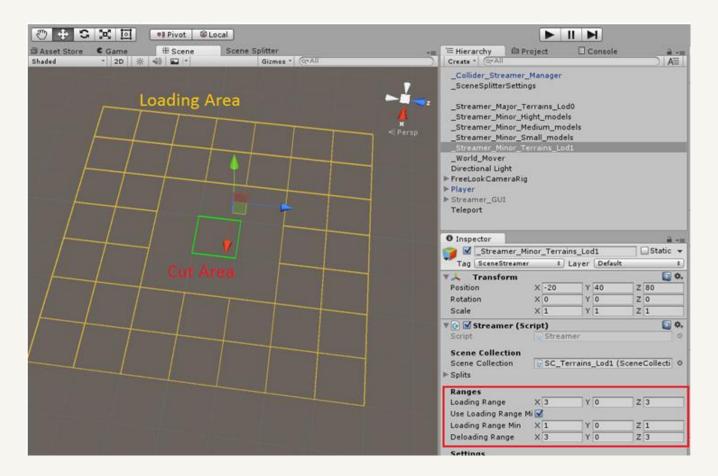

Loading range could be different for every axis in your world. If world is looped loading range must be shorter than half your world in virtual grid elements minus 1 virtual grid element.

• Use Loading Range Min, checkbox it allows you to use "Loading Range Min" we called this Ring streaming. This is our fresh system that allows you to load objects in specific range "from - to". We called it ring streaming because streaming area looks like ring. If objects are too close they will be removed, if they will be too far they also will be removed.

• Loading Range Min, (Ring Streaming) is an integer value in each axis that precise virtual grid elements radius that you want to cut out from "Loading Range". Streamer will load everything in the ring. If you will be close enough it will remove models from memory or doesn't load them. It's useful to replace models/objects in close distance by models/objects from other layers. When you click on Streamer object you could see gizmo at your screen with current loading range area. Look at image below, we have cut area, from loading area.

- Deloading range is an integer value that precise radius after which system will unload virtual grid elements(scene). Remember! Virtual grid element will be unloaded after time that you set in "Destroy tile delay", so first criterion is distance then time. If world is looped deloading range must be shorter than half of your world in virtual grid elements minus 1 virtual grid element.
- **Position check** is the position refreshing time in seconds. Streamer is loading/unloading your world saved in virtual grid elements(scenes) depending on followed object "Player/Camera" position in XYZ world.
- Destroy tile delay, value/time, in seconds, is useful to precise time, after which your virtual grid element(scene) will be unloaded from RAM memory, when virtual grid element(scene) will leave "Loading range". This value is useful when player is moving along the border of virtual grid elements or the player often moves between the same virtual grid elements. This will help you to avoid numerous load/unload actions in short time. This is also useful at "ring" streaming, old models will wait some time until they will be removed, in this time next layer will fill this place with other objects. For example Low Quality terrain mesh will be unloaded after 3 seconds but in this time Layer that holds High quality terrains will fill this area with its terrains. When low quality terrains will be removed, there will be no empty spaces. The same idea could be useful for models or other objects.

- Max Parallel Scene Loading is an integer value that gives you opportunity to decide how many virtual grid elements(scenes) you want to stream at the same time. This option is useful to optimize streaming. Low value will cause longer loading but you won't get any performance drop. You have to estimate and check few values of this to fit your purposes.
- Scene Load Wait Frames is value in frames useful to set delay between virtual grids elements loading. It's recommended to set few empty frames during streaming process, this will save streaming pipeline from overload. If you stream small virtual grid elements you could set 1 or 0. If time that you chose will be too long, streaming will be very slow only because of empty frames. You have to estimate and check few values this for your purposes.
- **Player** is place where you put object that represent player position for streaming system.
- **Terrain Neighbours** is place where you drag and drop object which contains "Terrain Neighbours" script. This will allow you to synchronize LODs between Neighbour terrains.
- Looping checkbox enables looping for this scene collection, this creates endless world. Each streamer with
 its scene collection is looped independently, which means if you want to synchronize them they must have
 the same world size. Carefully read <u>4.6 How to loop your whole world or specifyc object/models</u> section
 and example.

4.3 Teleport or Respawn

Drag and drop into your "Gameplay" scene "_PlayerTeleport: prefab. Player will be teleported into position that is equal to this prefab's XYZ coordinates. Fill streamers windows with all streamer objects that you use in this scene (from hierarchy). If you want to use loading screen at teleport/respawn, then fill "UI Loading Streamer" window. If you are going to use floating fix system please fill "World Mover" window. Below is the information about each setting, you will also find images with information about how to setup your respawn/teleport into your game.

- Ui Loading Streamer is a place where you can connect your UI canvas and loading screen with teleport/respawn system. This allows you to use loading screen system after player will be respawned or teleported. Simply drag and drop object from your scene hierarchy that contains UI Loading Streamer Script into this window. In our prefabs it's child of "Streamer_GUI" object.
- **Streamers** is place where you should put all streamer objects that you have at scene hierarchy. If you have more than one, grow up size and drag and drop all of them into this place.
- World Mover you should fill it by World Mover object (object that contains world mover script) from your scene hierarchy, only if you use floating point fix system.
- **Player** is a place where you drag and drop object from your scene hierarchy that represents player position for stream system. This object will be moved during respawn/teleport process.

Image with quick information how to setup respawn/teleport:

4.4 Loading Screen UI for game start/teleport/respawn

For start you could use our simple loading screen system. It contains loading progress bar and it's easy to apply. You also could use our scripts to build your own loading screen system and connect it to world streamer.

Drag and drop into your scene "Streamer_GUI" prefab or more simple "Loading_Screen_UI". "Streamer_GUI" is more advanced in relation to "Loading_Screen"UI", it contains additional things like "EventSystem", "Position_Gizmo", "LevelReset_Teleport_Button", and it also contains "Loading_Screen"UI". Fill "Loading_Screen"UI" with streamer objects from your scene hierarchy, which affect loading screen. In some cases not all streamers should affect loading screen. As an example we could give you small objects which are in memory only at close range, they are not so important so they could be loaded during gameplay.

- **Streamers** is a place where you should put all streamer objects that you have at scene hierarchy. In this place you should drag and drop only this streamers, which should affect loading screen. If you have more than one, grow up size and drag and drop all of them.
- Wait frame is a very important value in seconds, it should be higher than 1-2. This is the time that loading screen system need have to get info about how many virtual grid elements(scenes) from whole streamers will affect loading screen. If it will be too short loading screen could end before all virtual grid elements(scenes) are loaded, but if it will be to long you will simply waste time. Probably it should be about 2-3 seconds.
- **Progress Img**, here you drag and drop your image for progress bar if this window haven't been filed automatically or you want to change it.

4.5 Floating Point Fix system

If your game area is too big or you use looping system, you should use the floating point fix system. Basically if coordinates are too big in engine, physics and every unity system that is based on object position begins to lose accuracy in calculations. This may create strange situations in physics and create graphical bugs like flickering shadows. That's why we created system which removes this problem. World Mover will restart your world's position from time to time. While we use word "time" we mean a distance that is represented by virtual grid elements(scenes) interval. We have to use tile count/interval instead of xyz distance because it's easy and clear for whole system when restart should happen. You shouldn't restart world position too often because it's expensive process for most games. Floating Point Fix system also have solutions that support multiplayer games so check "current move" position.

Floating Point Fix system and Looping **do not support**:

- Static batching, because we are not able to move these objects at the moment unity blocks that. You could use custom batching system or batch your objects by combining them manually. You could use tools that are available at asset store. Your unity terrain should have static batching checked on, we are still able to move batched with static batching.
- Unity navmesh, until navmesh is not a gameobject that we could check, find, or get access to it and move. Until that we are not able to support it. You should use custom navmesh system like A*Star or Apex solutions, more about navmesh and AI is in "10. AI and navmesh solutions" section.

To add floating point fix system to your game simply drag and drop "_World_Mover" Prefab into your scene and fill it with all necessary information. If you use teleport/respawn system check "Important1" information below. If your camera is separated from the player or there are things that should have position reset together with the player like: camera, AI at single player, weather or sky horizon objects (which are not streamed by streamers, but need to hold them in relation to player position) please check "Important2" information which is below.

Position Gizmo			

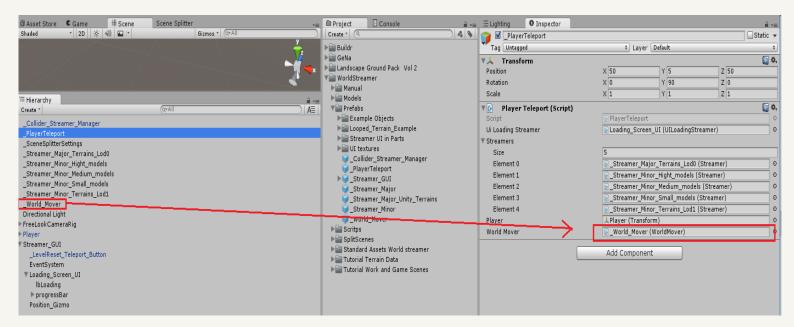

- **XYZ Tile Range**, it's used to set amount of virtual grid elements after which system will reset your coordinates. For example if tile range is "1"and major streamer has got each virtual grid element size 200x200 units, streamer will set 0,0,0 position to your player and to whole world after 2 virtual grid elements (we are counting from 0). This means after you move 400 units. So after each 400 units system will restart whole world position.
- Streamer Main, in this place you have to choose which streamer will decide how often system will reset your world position and which virtual grid (from which streamer) will decide when this will happen. We advice to use the streamer with the biggest virtual grid elements or if you stream unity terrain, you should use streamer with terrains.
- Streamers Additional, you should put here all the remaining streamers from your scene hierarchy, which should be affected by floating point system. In 99% cases you should drag and drop all of them.
- **Current move** is a difference between player's real and local position that is useful for correcting RPC with server communication or correct objects spawned from code. Local player position current move = real

player position. Local player position is the actual player game object position, it has been reset few times so that's why we call it as local.

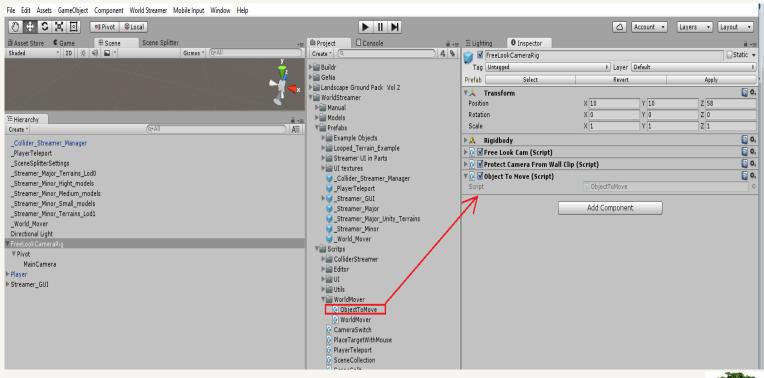

Important1!

If you use teleport/respawn system you have to connect "_World_Mover" object at your scene hierarchy to "_PlayerTeleport" prefab also at your scene hierarchy. Simply drag "_World_Mover" object from your hierarchy and drop into "_PlayerTeleport" script to "World mover" window.

Important2!

For objects that follow player or stay in important relation with the player or world we have "Object to move" script. Simply attach script to the objects that should follow player/world during position reset so that the relation between player and these objects will stay untouched. If you have particles that follow player or objects, please change their simulation space to local, or if this is not possible change that only for the moment of position reset. If you will not change this, particles will have small break because they need to spawn in new place.

4.6 How to loop your whole world or specific object/models

World streamer gives you ability to loop your world or imitate planet. That means, world could be endless like here:

Small Planet Demo <u>https://www.youtube.com/watch?v=WEnUypeT9vs</u> and you could curve it by this tool: Curved World https://www.assetstore.unity3d.com/en/#!/content/26165

Loop could be also used for repeatable things like asteroids in space.

To loop your world simply check the checkbox "looping" at your streamers in scene hierarchy. You should use floating point system for your looped world, so you also have to do everything that is in <u>"4.5 Floating Point Fix system"</u> section.

Looping checkbox enables looping for this scene collection, which creates endless world. Each streamer with its scene collection is looped independently, which means if you want to synchronize them they must have the same world size. **Carefully read the example**.

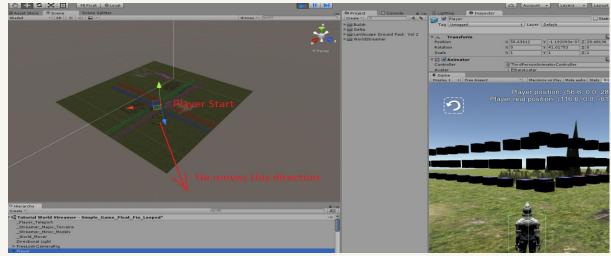

Example. We want to loop terrain layer that is -1000 to 6000 x -1000 to 6000 unit size. Each virtual grid has 1000x1000 size. So we have 7x7 grid. We want to synchronize model layer with these terrains, let them loop together. Model layer for example will have virtual grid element size = 50. Models must be spread at -1000 to 6000x -1000 to 6000 units area - they must have the same world size as terrains. If you have less models, you have to put empty objects at -999.99 and 5999.99 borders position for each axis. In our example X and Z axis. This will guarantee the same world area for both layers. As you see virtual grid elements of this both layers could have different size but their common world size -1000 and 6000 divided by virtual grid element size must be an integer value like in our example: Terrain layer: 6000/1000=6, -1000/1000=1; Model layer: 6000/50= 120, -1000/50= 20

In 1.8 world streamer version we will create layer synchronizing tool so you will don't have to do such things, like put empty objects to keep the same world size.

As we move world objects during looping, our loop system has the same limitations as Floating Point Fix system. Floating Point Fix system and Looping **do not support**:

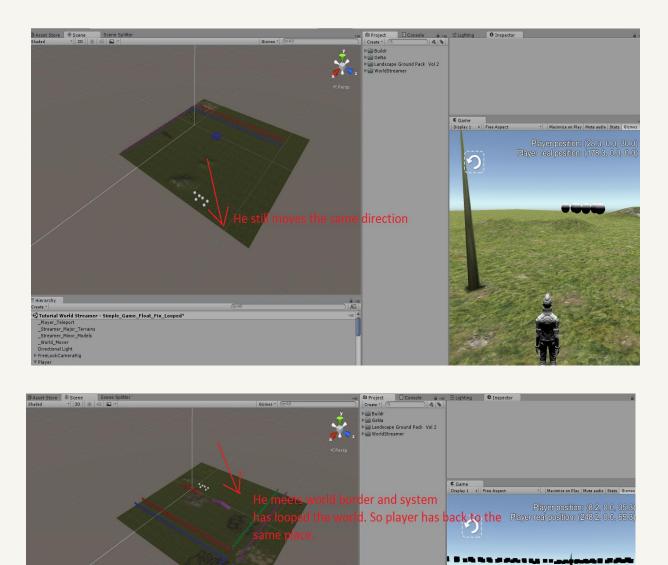

- Static batching, because we are not able to move these objects at the moment unity blocks that. You could use custom batching system or batch your objects by combining them manually. You could use tools that are available at asset store. Your unity terrain should have static batching checked on, we are still able to move these batched terrains.
- Unity navmesh, until navmesh is not a gameobject that we could check, find, or get access to it and move.
 Until that we are not able to support it. You should use custom navmesh system like A*Star or Apex solutions, more about navmesh and AI is in "10. AI and navmesh solutions" section.

Here is an image that shows how looping system idea works:

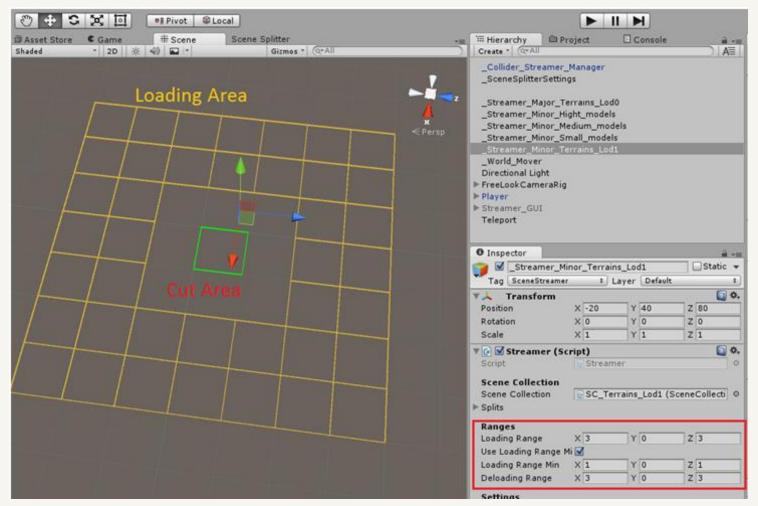

4.7 Ring streaming idea

- Simple Game Float Fix Loope

This is our fresh system that allows you to load objects in specific range "from - to". We called it ring streaming because streaming area looks like ring. If objects are too close they will be removed, if they will be too far they also will be removed. Ring streaming could be useful to replace objects at close or far distance. If 1st streamer will stream layer with high quality detailed objects/terrains only at short distance, then 2nd streamer could stream low quality objects/terrains at far distance only. Low quality objects/terrains will disappear in place where high quality objects/terrains will be loaded. You will get far view with extremely good performance. This is very good solution if object - like unity terrain doesn't support LOD system and its data (regardless of visibility) is very heavy to load. The second case is when object like unity terrains - object generates static CPU usage or performance drop while refreshing process.

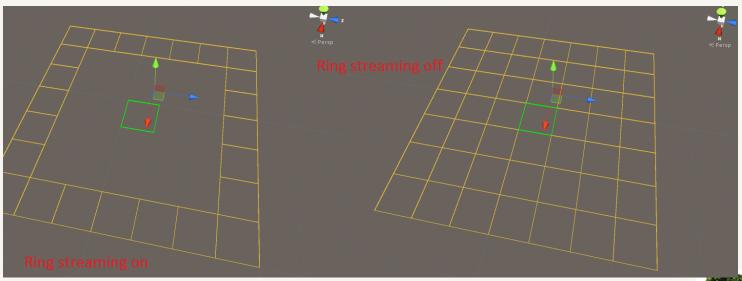

To turn on "Ring streaming" simply check "Use Loading Range Min" at your streamer object in hierarchy and fill "Loading Range Min values".

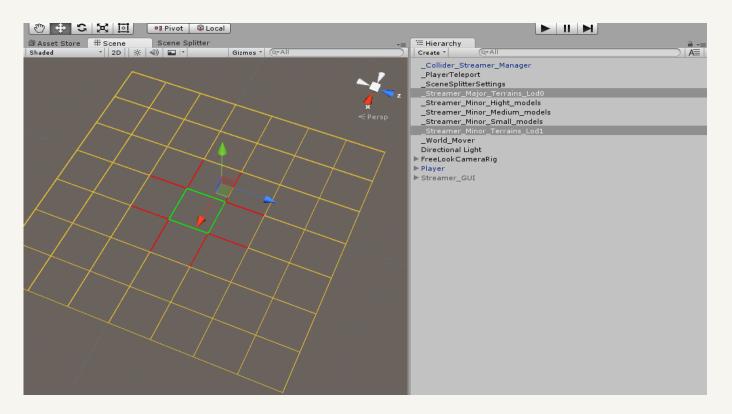

- Use Loading Range Min checkbox allows you to use "Loading Range Min" which we called Ring streaming.
- Loading Range Min (Ring Streaming) is an integer value in each axis that precise virtual grid elements radius that you want to cut out from the loading range. Streamer will load everything in the ring. If you will be close enough it will remove or doesn't load objects from memory. It's useful to replace objects in close distance by other layers. When you click on Streamer object you could see gizmo at your screen with current loading range area, like you see at the image above..

Here is streamer gizmo from ring streaming ON and OFF:

Here is streamer gizmo, from 2 streamers which complement each other. On first ring streaming is ON and it streams low quality terrains Lod1 (yellow), on second is OFF and it stream high quality terrains Lod0 (red):

5. Terrain Streaming

First of all, there are few things that need to be said before you start to stream your terrain. If you want to stream unity terrain, it must be in parts. Each unity terrain part generates static CPU usage and dynamic when you load next tile. All of this performance eaters could be solved or reduced. Information about how to solve/reduce this, you will find in <u>"5.5 Huge amount of details at unity terrain and performance solutions"</u> section. Terrain in our system could be looped and replaced by low poly meshes in far distance. Read carefully whole info that we give you in <u>"5. Terrain Streaming"</u> section, it could save you a lot of time and guarantee extremely good performance in relation to any other available solutions.

There will be a lot of text like you probably see but everything must be clear. After this tutorial you will be able to work/refresh/add/remove streamed terrains very fast.

5.1 Terrain preparation (unity terrain, low poly mesh, custom solutions)

To stream your terrains you have prepare them for this process.

 When you are starting with unity terrains you need terrains in parts/chunks. You could cut one big terrain into chunks by: Free tool

http://kostiantyn-dvornik.blogspot.de/2013/12/unity-split-terrain-script.html World Composer https://www.assetstore.unity3d.com/en/#!/content/13238

Remember to leave your source terrain untouched because you could change your mind about virtual grid element size!

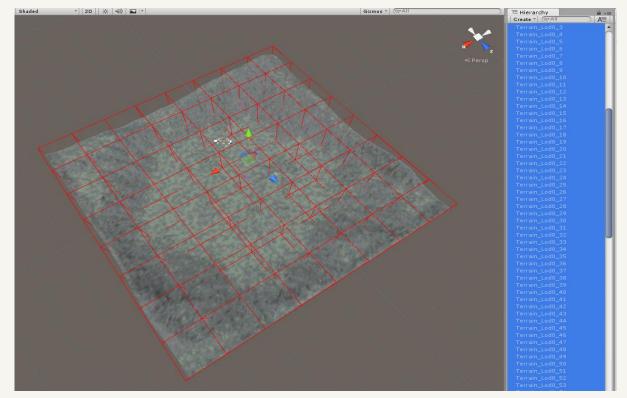

You could generate your world already in tiles by: World Creator Professional (our close friends and we are in cooperation): <u>https://www.assetstore.unity3d.com/en/#!/content/55073</u> World Creator Standard (our close friends and we are in cooperation): <u>https://www.assetstore.unity3d.com/en/#!/content/54631</u> Terrain Composer 1/2 (we are also in cooperation with Nathaniel for very long time) <u>https://www.assetstore.unity3d.com/en/#!/content/65563</u> Gaia (we are also in cooperation, tilling is planned in 08.2016) <u>https://www.assetstore.unity3d.com/en/#!/content/42618</u>

Developers always ask how big this terrain chunks should be? Basically it's your choice we could give you a few tips, depending on way that you chose.

- (a) If you don't want to use ring streaming and low poly mesh at far distance instead of unity terrain, your each terrain tile should be size 110% of your camera far view. This will guarantee low static cpu usage, because you will set loading range to 1 and only 9 terrain tiles will be loaded. If you have a lot of foliage you could get unity terrain dynamic culling spike during next tiles loading which is unity terrain bug. It refresh whole foliage at all terrains at one moment what is a well known mistake. Unity works on this and they are going to fix it someday. Such big tiles also mean quite big memory consumption but not tragic and quite big CPU consumption from static culling (many tree objects). We advise size 110% of camera far view because probably nobody wants to see how terrains are loading (appear). This could happened from time to time. With 110% you leave this 10% of "time" for loading process. Basically this option is not tragic but only when you don't have huge amount of foliage at your terrains. Static culling CPU usage could be about 0.5 3 ms, dynamic culling CPU spikes from loading could be about 3-100ms. In section "5.5 Huge amount of details at Unity terrain and performance solutions" you will find few ways to optimize or remove performance problems.
- (b) If you use ring streaming to replace far terrains by low poly mesh which is much, much better solution, your terrain chunks/parts should be 10-50% of camera far view. 10% is good if you want to have control on terrain details by in game options. 30-50% is good if you just want to leave terrains like they are. Advantages of this solution is that you have very far view and you spent only few verts/tris and 1 drawcall per each low poly mesh as terrain. You could handle many terrain tiles because many of them are simple meshes and unity terrains are small, they hold smaller amount of data and their refreshing time is short. By Streamer loading range and loading range min you could adjust when your terrain will become low poly mesh. This is dynamic option so could be changed during gameplay. Player could choose the level of details.
- (c) If you use only low poly mesh instead of unity terrains (probably mobile games), you could use any size but remember to engage number of tiles with camera far view. It's good to hold amount and size of loaded tiles in relation 110% of camera far view, only because of terrain appears/show on. You left this 10% of "time" for loading new tiles.

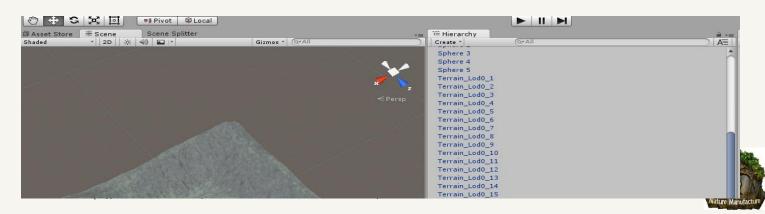

Custom terrain solutions are always difficult because we don't test all of them so probably it will be combination of "b" and "c" point in this section.

2. We can move to next step when your terrains are in parts like this:

- 3. First terrain should have a starting position XYZ from full rounded position like : 5000, -5000, 0, 1000, 500, -100 etc not like 99.98, 0.1, -0.018. This kind of wrong positions, could effect in unexpected terrain offsets in virtual grid elements. Remember virtual grid elements starts from 0, 0, 0 and unity terrain pivot is in it's corner, this sometimes could effect in offset between terrain and virtual grid borders. You could simply remove this offset by placing terrains on positions which are multiples of their size. For example if terrain tile size is 500x500, virtual grid element size is 500x500, then terrain objects must lie on positions like 500, 0, -500, 1000,-1000 and other multiples of 500. This will synchronize virtual grid elements with terrains.
- 4. Rename your terrain objects by adding word "Terrain_LOD0_" at their names beginning or "Terrain_LOD1_" for low poly terrain mesh. Of course this could be any word, we give just an example. This word will be used during splitting/segregation process which put's terrains in correct virtual grid elements and layers. You could use this free asset to rename your terrain objects, it is easy and fast: Ez Files Rename https://www.assetstore.unity3d.com/en/#!/content/31082
- 5. Create prefabs from these terrains, this is not necessary but it gives access to them without opening the scene so it's useful. You could create prefabs when you will be sure that terrain parts size are fit for your game. Probably you will be sure of them after you will see how streaming goes.
- 6. Unpack your terrains from all mother/parent folders like at this screen:

5.2 Scene split and virtual grid setup

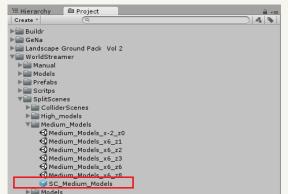

When your terrains are prepared like in <u>"5.1 Terrain preparation"</u> section, you are ready to split them, which means we are going to put them into correct virtual grid element automatically. Now you should follow this steps:

- 1. Open empty scene and save it, then you should copy your terrains here. You could call this scene as "Work" scene.
- 2. Open "Scene Splitter" window by clicking at World Streamer =>Scene Splitter

File Edit Assets GameObject	Component Mobile Input Asset Store Tools	World Streamer Window Help
🖑 🕂 S 😤 🔟	💵 Pivot 🛛 😨 Local 🖉	
Came #Scene		= Scene Splitter
Shaded * 2D 🔆	④ ▲ ▼ Gizmos ▼ Q▼All	Scene Splitter
		Split scene by: Split x

- 3. Fill scene Splitter window:
 - Click add layer button
 - Check "Split X" and "Split Z" don't check "Split Y" axis if it is not so important for streaming (like in Space Games). If you don't want to remove terrains because of player Y position don't check "Split Y" axis.
 - Fill X,Z, optional Y size. Size MUST be equal to terrain size. If your terrain is 200 width, 300 length please fill "X size" with 200 value and "Z size" by 300
 - Fill GameObject Prefix by word that we add to our terrains names, so "Terrain_LOD0_". Splitter will check all objects at the scene and if any object will contain "Terrain_LOD0_" at the beginning of the name, splitter will use it in this layer.
 - Fill Scene Prefix (layer name) by name that will be clear for you, it could be: "High_Quality_Terrain" or you also could add info about which world it belongs to, if you got more than 1 world. So name with this info will look like: "World_1_High_Quality_Terrain".
- 4. If you are sure about everything that you filled in Splitter window, you could click "S" button or "Split Scene". You could undo that operation by "C" button or "Clear Scene Split". System during split will prepare virtual grid elements/future scenes from your chosen assets. For more info about this section <u>"4.1 Scene Splitter"</u>
- 5. If you are sure about virtual grid elements that system made, click "Generate Scenes from virtual Grid". This is the last thing that you have to do with your assets. System will start generating scenes from virtual grid elements. It will create scenes in specified directory or in default one. System will also create scene collection prefab called "SC+Scene Prefix". In our example we will get scene collection prefab called: "SC_World_1_High_Quality_Terrain" or "SC_High_Quality_Terrain". This file contains all fresh info about

your scenes (virtual grid elements): how many are they, how they were split, when they start and end (world borders). This important scene collection prefab called "SC+Scene Prefix" will be connected by us to streamer objects at your "Gameplay" scene. It allows you to stream this whole content in proper time and place.

5.3 Streamer setup at your game scene

After everything in <u>"5.2 Scene split and virtual grid setup"</u> section is done and we have our "SC+Scene Prefix" scene collection or collections (if we made the same with low poly terrain but with other scene and object prefix), we could start to setup our "Gameplay" scene. For start we should open/create empty scene with player, camera and directional light and follow these steps:

- Drag and drop into your "Gameplay" scene "_Streamer_Major" prefab. We use _Streamer_Major because in 99% cases terrain is the main streamer. If you are going to add also model streaming, models should use "_Streamer_Minor".
- 2. Check if it has "SceneStreamer" tag! Without this it could not work or simply doesn't run at build.
- 3. Drag and drop into your game scene "_Streamer_GUI" prefab. This prefab contains graphical UI, Loading Screen, Teleport/Respawn and gizmo "Position" viewer for floating point fix or looping system.
- 4. Click on _Streamer_Major at your scene hierarchy. Drag and drop your scene collection "SC+Scene Prefix", that you made in <u>"5.2 Scene split and virtual grid setup</u>" section into "Scene Collection" window. In our example it was: "SC_World_1_High_Quality_Terrain" or "SC_High_Quality_Terrain". Scene collection prefab is in catalogue with generated scenes, which it belongs to, so WorldStreamer→SplitScenes→Layer name (SC_High_Quality_Terrain or SC_World_1_High_Quality_Terrain)
- 5. By this moves you connected your generated scenes with streamer.
- 6. Fill streamer settings according to "4.2 Streamer objects" section. For this manual example we will set:
 - Loading range to X= 1, Y = 0, Z = 1
 - Use Loading Range Min = false
 - Deloading Range X= 1, Y = 0, Z = 1
 - Destroy Tile delay = 1 second
 - Position check time = 0.1 seconds
 - Max Parallel Scene Loading = 1
 - Scene Loading Wait frames = 2 frames
 Summing that means we will load area 3x3 of terrains parts/virtual grid elements/scenes and unload every virtual grid element that is further than this. We will check our position every 0.1 second.
 Streamer will load max 1 terrain part during one frame and we left 2 frames to finish asynchronous stream operation after each virtual grid element was loaded and before we load next one.
 - We fill "Player" window by draging and droping our player from scene hierarchy into "Player" window. Our system will follow that player and load terrain tiles if they will be close enough.
- 7. Now we will set up our UI if we want to use loading screens.
 - Drag and drop "_Streamer_GUI" or "_Loading_Screen_UI" from project into scene hierarchy.
 - We click at "_Loading_Screen_UI" object (child of "Streamer_GUI") in scene hierarchy and we write Size =1 or more (if we have more streamers) in Streamer value.
 - Now we need to drag and drop our "_Streamer_Major" from scene hierarchy as element 0 in "UI Loading Streamer Script". Element 0 holds high quality terrains. Loading bar in loading screen will release player into game only when all scenes from element 0 will be loaded.
- 8. If we use unity terrains we should add Terrain Neighbour script to "_Streamer_Major" object at your scene hierarchy and then drag and drop this script into "Terrain Neighbours" window at streamer script. This will

blend LOD edges at terrains borders. It will remove small holes that came from unity terrain LOD system. If you want to stitch big differences at your terrains check <u>"5.6 Workflow solutions for terrain pieces"</u> section.

9. We click at "_Streamer_Major" game object and if we didn't added our scenes from scene collections to the build setting, we should see a warning with button. Click on it and system will automatically add missed scenes to the build settings. Each time you change number and size of virtual grids elements you have to click that button!

Looping	
Add scenes from scene collection to build settings.	
	Add scenes to build settings

10. Click play and it works!

Important1.

Now you could easily split/unsplit/add new terrains/remove content/move content and you could refresh layer with terrains and streamed world in few seconds by clicking split and then generate againm at your work scene or by our "local area updater". System will refresh your scenes. You only need to refresh "_Streamer_Major/Minor" prefabs by clicking add to build settings button. That means you could easily test many configurations!

Important2.

When you modify your terrains, by adding plants, changing shape, painting textures you don't have to split again your scene and refresh your streamers. Terrains are saved at scene and they hold reference to your terrain data. That mean everything will be actual all the time.

5.4 Ring streaming and how to replace detailed terrain object by low poly mesh at far distance

In <u>"4.7 Ring streaming idea</u>" section we showed you how ring streaming could be used. Here we will go to the practice. Our goal is to change detailed terrains/unity terrains into low poly mesh at far distance.

 First of all we need detailed terrains like unity terrain objects, they must be in parts. Please complete <u>"5.1</u> <u>Terrain Preparation"</u> section. In result of it you should have many terrain parts. Now we need to change them into low poly meshes. To do that you need for example "Terrain To Mesh" solution, which is available at unity asset store: <u>https://www.assetstore.unity3d.com/en/#!/content/47276</u>

By using this tool, you could generate low poly terrains from unity terrain objects. You can choose vertex count (please set it low). We set 25x 25 =625 vertexes at our demo and it's fine. It could be even lower because unity terrain at "pixel error" = 20 has less vertexes than low poly mesh. Very important thing is to choose splatmap shader or simple texture. In our opinion you should generate one RGB texture and set it into standard shader instead of layers with splatmaps which are expensive. 1024x1024 texture size is enough for far view terrains. We should generate this mesh and texture for each terrain part/chunk that we have. You could also generate terrains with trees! You will not loose trees in far view. This kind of terrains you could find at our "Advanced_Work_Scene", we called them "Terrain_Lod1"

Center S Local

errain Lodt 21		Shader Standard				

Unfortunately you have to regenerate this low poly terrains each time you've made big changes. It takes only few moments so this shouldn't be a problem. Probably you could automate that, by adding small script.

Now we have to rename our assets, we must have order and we also need to setup prefix for our terrains like in <u>"5.1 Terrain Preparation"</u> section. Rename your low poly terrain objects by adding word "Terrain_LOD1_" at their names beginning. This will be used during splitting/segregation process which will automatically put terrains in correct virtual grid elements and layers.

Example.

 $Game object {\rightarrow} {\sf Terrain_LOD1_Game object}$

- 2. Creating prefabs from these terrains is not necessary, but it gives access to them without opening the scene so it's useful. You could create prefabs when you will be sure, that terrains fit your game. Next advantage of prefabs is that you could replace mesh, material, texture. So any changes will not cause necessity of splitting and regenerating your scene again. You could easily fix/actualize your terrains by modifying prefabs.
- 3. When your terrains are ready, you should open scene splitter window. Open "Scene Splitter" window by clicking at World Streamer =>Scene Splitter

File Edit Assets GameObject Component Mobile Input Asset Store Tools World Streamer W	indow Help
🖑 💠 S 🔀 🔟 💷 Pivot 🔹 Local	
Came # Scene *=	Scene Splitter
Shaded * 2D 🛛 🔅 📣 🖬 * Gizmos * 🖓 All	Scene Splitter
×	Split scene by: Split x 🗹

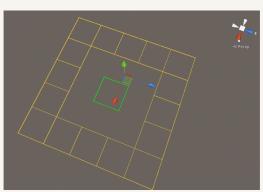

- 4. Fill scene Splitter window:
 - Add layer
 - Change his gizmo color into yellow.
 - Check "Split X" and "Split Z" don't check "Split Y" axis, if it is not so important for streaming (like in Space Games). If you don't want to remove terrains because of player Y position don't check "Split Y" axis.
 - Fill X,Z size and optionally Y size but only if you checked Y axis. Size MUST be equal to terrain size. If your terrain is 200 width, 300 length please fill "X size" with 200 value and "Z size" by 300
 - Fill GameObject Prefix by word that we add to our terrains names, so "Terrain_LOD1". Splitter will check all objects at the scene and if any will contain "Terrain_LOD1" at the beginning of the name, it will use it in this layer.
 - Fill Scene Prefix (layer name) by name which will be clear for you, it could be the same name as layer like: "Low_Quality_Terrain" or you could add kind of info about which world it belongs to, if you got more than 1 world. So name with that info will look like: "World_1_Low_Quality_Terrain".
- 5. If you are sure about everything that you filled in Splitter window, you could click "S" button or "Split Scene", you could undo this operation by "C" button or "Clear Scene Split". System during split will prepare virtual grid elements/future scenes from your chosen assets. If you want more information about this operation check section <u>"4.1 Scene Splitter"</u>
- 6. If you are sure about virtual grid elements that system made, click "Generate Scenes" button. This is the last thing that you have to do with your assets. System will start generating scenes from virtual grid elements and layers. It will create scenes in specified directory or in default one. System will also create scene collection prefab called "SC+Scene Prefix". In our example we will get scene collection prefab called: "SC_World_1_Low_Quality_Terrain" or "SC_Low_Quality_Terrain". This file contains all fresh info about your scenes like: how many they are, how they were split, when they start and end (positions). This important_

scene collection prefab called "SC+Scene Prefix" will be connected by you to streamer objects at your game scene. It allows you to stream this whole content in proper time and place. This scene collection prefab "SC+Scene Prefix" will be stored in catalogue with generated scenes. In our example WorldStreamer→SplitScenes→"SC_World_1_Low_Quality_Terrain" or "SC_Low_Quality_Terrain".

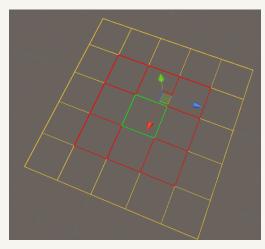

- Open your "Gameplay" scene, where you configured your streamers with high quality terrains. Check: <u>"5.3</u> <u>Streamer setup at you game scene"</u> section for more information.
- 8. Drag and drop into your game scene "_Streamer_Minor" prefab. We use "_Streamer_Minor" because in 99% cases low poly terrains with ring streaming use minor streamers. High quality terrains will manage streaming process, low quality terrains are only their LODs.
- 9. Check "SceneStreamer" tag at your streamers! Without this it could not work or simply doesn't run at build.
- 10. We already have "_Streamer_GUI" prefab at the scene from <u>"5.3 Streamer setup at you game scene"</u> section.
- 11. Click on "_Streamer_Minor" at your hierarchy. Drag and drop your scene collection "SC+Scene Prefix", this which you prepared few minutes ago so it was called: "SC_World_1_Low_Quality_Terrain" or "SC_Low_Quality_Terrain" in our example.
- 12. By this move you connected your generated scenes with streamer.
- 13. Fill streamer settings. Take a look at differences between this streamer and major streamer. They are very important.
 - Loading range to X= 2, Y = 0, Z = 2. It must be bigger than major streamer loading range.
 - Use Loading Range Min = true! This steamer will stream in ring
 - Loading range min to X = 1, Y = 0, Z = 1. It must be equal to major streamer loading range. Here is the place where system will replace high quality terrain by low quality terrains, it will happen at border between 1 and 2 virtual grid element/scene counting from player position.
 - Deloading Range X= 2, Y = 0, Z = 2. Must be equal or bigger than loading range.
 - Position check time = 0.1
 - Destroy Tile delay = 3. We need time, high quality terrain could load slow, so itneed time to show up/load. If this time value will be too small, you will get empty spaces for a while. This could happen in moment when new high quality terrain was not loaded yet, but old low quality was removed already.
 - Max Parallel Scene Loading = 2 or more. Scenes are simple and they will not take much CPU time during loading.
 - Scene Loading Wait frames = 1. Scenes are simple and they will not take much CPU time.

Summing up that mean our minor streamer will load ring area like in this gizmo:

Our major streamer will fill that empty space in the middle. You could check both streamers (minor and major) at your hierarchy and gizmo should looks like this:

Yellow is our minor streamer, red is major.

- Click again at our minor streamer. Now we will fill "Player" window, by dragging and dropping our player object from scene hierarchy into "Player" window. Our system will fallow that player and load terrain tiles if they will be close enough to the player.
- 14. Now we will fill our UI if we want to use loading screens.
 - We click at "Loading_Screen_UI" object at "Streamer_GUI" in scene hierarchy and we type Size =2 in "Streamers" value which you could find in "UI Loading Streamer Script".
 - Now we need to drag and drop our "_Streamer_Minor" from scene hierarchy as element 1 in "UI Loading Streamer Script". From this moment we have "_Major_Streamer" as element 0 and "_Minor_Streamer" as element 1. Element 0 holds high quality terrains, element 1 holds low quality terrains. Loading bar in loading screen will release player into game only when all scenes from element 0 and 1 will be loaded.
- 15. We click at "_Streamer_Minor" game object and if we didn't added our scenes from scene collections to the build settings, we should see a warning with button. Click on the button and system will automatically add missing scenes to the build settings. Each time you change number and size of virtual grid elements you have to click that button!

Looping		
Add scenes from scene collection to build settings.		
Add scenes to build settings		

16. Click play and it works!

Important!

Now you could easily split/unsplit/add new terrains/remove content/move content and you could refresh layer with terrains and streamed world in few seconds, by clicking split and then generate again at your work scene or by our "local area updater" tool. System will refresh your scenes and "_Streamer_Minor" at your game scene. It only needs to be refreshed by clicking add to build settings button. That mean you could easily test many configurations! If number of scenes has not changed and everything is all right, this button will not show up.

5.5 Huge amount of details at Unity Terrain and performance solutions

It is possible to stream terrains with huge amount of details without any CPU spike. There are few problems which you probably are going to meet with:

- 1. CPU culling spike after you load new virtual grid element with terrain that contains huge amount of trees. If you have spike during loading, you probably also have big static CPU usage (1-3ms) because of culling (tree and terrain refreshing). There are few ways to remove/reduce it:
 - You could use ring streaming, low poly terrains could contain trees.
 - Turn of terrains rendering that are not visible, by your own or our script "TerrainCullingSystem" Simply drag and drop it on each terrain prefab/object and set max visibility distance for this terrain. (Unity 5.3+)
 - Both solutions, ring streaming and culling by script.
 - Tree manager system, but we haven't tested it. Here is link to the asset store <u>https://www.assetstore.unity3d.com/en/#!/content/43129</u>
- 2. CPU spike after you load virtual grid element with terrain that contains huge amount of grass. You could find that in CPU→Culling→Terrains→... This is most problematic, it is a unity bug! When you load next part of your terrain, unity refresh all terrain details at your scene. They will fix that in few months, unity terrain team know the bug. Until this bug is present, there are few solutions that will remove or reduce it.

 - You could use ring streaming, low poly terrains don't need grass, so they will not going to be refreshed and generate spikes.
 - Turn of terrains that are not visible by our or your own script. Our script is not included, contact our support email if you want to try it. This solution will only reduce spike. When terrain is turned off, it is not refreshing during streaming.
 - All solutions or their combinations: ring streaming, culling by script and uNature.

If you will use listed in points "1" and "2" tips, your terrain could get extreme performance boost (CPU,RAM,VRAM,GPU) and not only during loading. These tips are useful not only to reduce spikes. They reduce static terrain CPU and memory usage a lot! By using this solution you could render your terrains in very far view even at mobiles!

If you left low amount of objects (detailed terrains) at the scene, some scripts could work faster. When you call garbage collector, his spike will be reduced to value that you could skip. If you want to remove objects from memory you have to call GC (garbage collector) from time to time. We call it in our system, you always could change calling density in our code.

If texture streaming is slow/generates spikes, please adjust "Async Upload Time Slice" and "Async Upload Buffer Size" in Quality settings.

So too summing up, we use unity terrains for close distance with grass and tree managers, we could turn off terrains that are not visible at your camera (smart culling script). For far distance we use low poly meshes with baked trees. In this setting we could remove millions of vertexes and hundreds of drawcalls. Your loading will be smooth, it will not affect players CPU. Memory usage will be very low probably you will cut few hundreds of MB that you could

spent on textures and models. Isn't that promising? It is and this is how console and MMO, AAA games works and handle terrains and models.

5.6 Workflow solutions for terrain in pieces

In manual we said that you must split your terrains into parts. Probably after that you still need to work at them. When terrains are in parts it's really hard to work on their borders. It's annoying to switch between them, correct their borders. We made solutions for that.

Multiple Terrain Brush

It gives you ability to work on many terrains like it was a single one. You don't need to switch from terrain to terrain. Our brush gives you ability to blend edges by marker.

Link: https://www.assetstore.unity3d.com/en/#!/content/44037

Terrain Stitcher

This is our advanced math tool. It could stitch/blend edged of many terrains at once. You have many functions that could repair/blend your terrains in many different ways, just take a look: Link: https://www.assetstore.unity3d.com/en/#!/content/42671

5.7 Create looped terrain

Probably small amount of developers want to create endless looped world with terrains, something like a planet. Wherever you go you will eventually come back to the same point. That means world will be endless like here:

World Streamer Small Planet Demo: https://www.youtube.com/watch?v=WEnUypeT9vs

and you could curve it as we do it by this tool:

Curved World: https://www.assetstore.unity3d.com/en/#!/content/26165

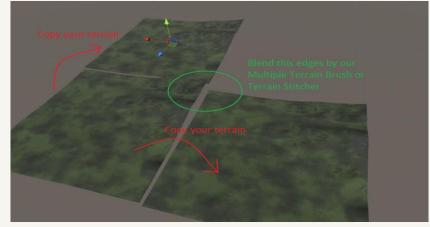

With our tools and world streamer it will be very fast and easy to do. First of all you need Multiple Terrain Brush or Terrain Stitcher to blend your terrain/terrains edges.

Link: https://www.assetstore.unity3d.com/en/#!/content/44037

Link: https://www.assetstore.unity3d.com/en/#!/content/42671

There are two moments when you could loop your terrains:

- 1. You have your terrains in one chunk, you didn't split it yet. Probably it's easiest way.
 - Simply copy and move your terrain like in this image (yes you to need blend only 2 borders):

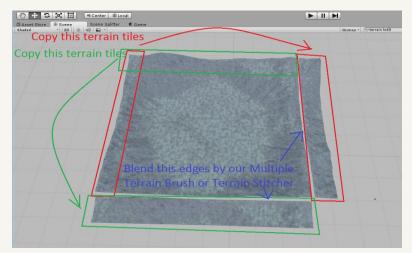

Borders must be in contact. That means if terrain ends at position 200, next (copied) terrain must start from position 200.

• Start Multiple Terrain Brush or Terrain Stitcher and simply blend your terrain edges by our tools.

- When you finish, remove additional terrains (which were copied only to have perfect terrain borders) and terrain is ready!
- Do all points from <u>"5.1 Terrain preparation</u>", <u>"5.2 Scene split and virtual grid setup</u>" sections. At <u>"5.3 Streamer setup at your scene</u>" section, the only change is that you have to check checkbox "looping" at your "_Streamer_Major" in gameplay scene hierarchy.
- If you also want to use ring streaming you have to do all points from <u>"5.4 Ring streaming"</u> section and also check checkbox "looping" at your "_Streamer_Minor" in gameplay scene hierarchy.
- Probably you should use floating point fix system. You have to use it, because while player will move over your world all the time in one direction, his position XYZ will still grow. If position will be too big physics, shadows will stop working properly. Please check <u>"4.5 Floating Point Fix System"</u> section to add this. It's easy and it will only take you few minutes/seconds to setup.
- Done, you have your world looped, hit play and test!
- 2. You have your terrains in many parts
 - Simply copy and move your border terrains like in this image:

Borders must be in contact. That means if last original terrain ends at position 200, next (copied) terrain tile must start from position 200.

- Start Multiple Terrain Brush or Terrain Stitcher and simply blend your terrain edges by our tools
- When you finish, remove all additional terrain tiles (which were copied only to have perfect terrain borders)
- Your terrain data at these terrains have been actualized.
- Do all points from this list, but only if you haven't done theme before:
 - <u>"5.1 Terrain preparation"</u> Probably you have done it before, because you have your terrains in parts.
 - <u>"5.2 Scene split and virtual grid setup"</u>, if you haven't split your terrain tiles before.
 - <u>"5.3 Streamer setup at your scene"</u> section, the only change is that you have to check checkbox "looping" at your "_Streamer_Major" in "Gameplay" scene hierarchy.
- If you also want to use ring streaming you have to do all points from <u>"5.4 Ring streaming"</u> section and also check checkbox "looping" at your "_Streamer_Minor" in "Gameplay" scene hierarchy.
- Probably you should use floating point fix system. You should use it because while player will move over your world all the time in one direction, his position XYZ will still grow. If position will be too big physics, shadows will stop working properly. Please check <u>"4.5 Floating Point Fix System"</u> section to add floating point fix system. It's easy and it will takes you only few minutes/seconds to setup.
- Done, you have your world looped, hit play and test!.

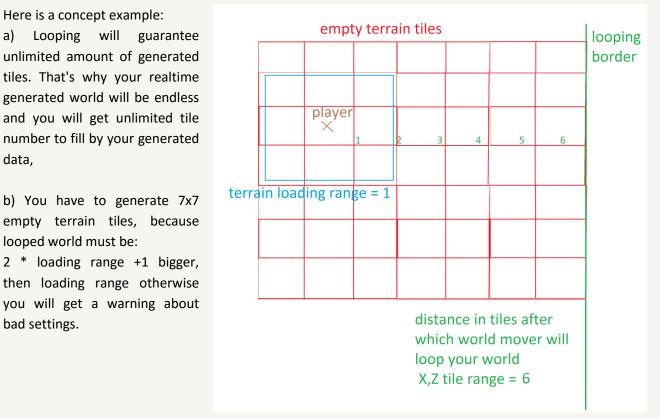

5.8 Real-time generated terrains support

There is possibility to stream real-time endless generated terrains. We will discuss this very short, here is the idea of how to handle this and use world streamer. We discussed this idea at forum and we would like to share the result.

 You have to create big group of empty terrains. You must generate 2,5x more terrain tiles then you want have loaded at one time, this because of looping system. Place them as grid and split with proper settings. Check sections: <u>"5.1 Terrain preparation (unity terrain, low poly mesh, custom solutions)</u>" and <u>"5.2 Scene split and virtual grid setup"</u>.

- 2. Then you have to generate scenes, check: "5.3 Streamer setup at your game scene" section.
- 3. Check looping at streamer prefab, you could also use floating point fix system which optional.
- 4. When your blank terrain streaming is ready, you have to modify our world streamer script or attach your own script to blank terrains (probably easiest way). You have to fill/replace every blank terrain by your data generated from runtime generator. This will work properly.

Of course you could create your own idea how to merge terrain streaming with real-time generation. If you have it, you could share your idea with us, so we could discuss it.

6. Model/Objects Streaming

Models and objects streaming is the main feature of World Streamer. With our solution you are able to read from the disc your objects that have been placed in your world and split into virtual grid and layers by our splitting tool. Our splitting system will easily refresh, grow, reduce your world library (virtual grid elements/scenes). You can put huge amount of different objects like: lights, particles, models, colliders, reflection probes and everything will be read from the disc in the proper moment. We highly advice you to stream objects/models in layers. This give you ability to get better performance and optimize some unity functions that are not supported by unity LODs system. Of course everything is compatible with unity LOD system but we offer much more. If you left low amount of objects at the scene some scripts could work faster. When you call garbage collector, its spike will be reduced to value that you could skip. If you want to remove objects from memory you have to call GC (garbage collector) from time to time.

Optimization which we are talking about are specially touching particles and lights. As you had seen or not, if you put Lights or Particles at unity LODs system, when become culled but:

- Lights are still active and give light and grow drawcalls at objects that they touch.
- Particles are still active at CPU. If you check profiler your particles will still take CPU because of update and generating process

All this CPU,RAM,VRAM,GPU usage could be remove by world streamer. Light and particles will only use your sources when they become close enough to be visible.

If texture streaming is slow/generates spikes which calls "GFX wait for present" please adjust "Async Upload Time Slice" and "Async Upload Buffer Size" in Quality settings.

Let's get back to our objects and streaming. This small tutorial will help you to stream your objects during gameplay. There will be a lot of text like you probably see, but everything must be clear. After this tutorial you will be able to work/refresh/add/remove streamed models/objects very fast.

6.1 Model/Object preparation

We always advise you to open/create empty scene that we will call "Work" scene, copy your whole content (which you want to stream) there. Directional lights, player, UI should be at your game scene, so remove them from this scene or hide during splitting process. If you will properly set your layers, this objects could stay here.

- 1. Think about in how many layers you would like stream to your objects. Everything depends on your game style. We will give example for GTA style game. This will help you to visualize layer and streaming idea. We recommend you to use architecture like this:
 - Big objects their shape is visible from long distance (buildings, roads, huge rock structures).
 - **Medium objects** objects that are quite big and it's important to see them in quite long distance (static cars, building add-on, fences, lanterns, bushes, boxes, street signs)
 - **Small objects** objects that are really small, not important, details. (papers, dirt, street wells, flowers, trash, dumpsters, small street signs)
 - Lights and Particles you could put them at medium or small objects but also create individual layer for them.

If you create RTS game or game with top down view, you will probably use only one layer or less than this list above. For space game you should separate stars from planets, asteroids etc... Simply you should have catalogued objects by size and visibility distance. Anyway number of layers is your independent choice.

2. After you have decided how many layers you are going to use, you should rename your objects at the scene by giving them additional word at object name beginning. We call this as prefix in further doc parts. You should start from prefab renaming. When you rename your prefabs in project, objects at scene hierarchy also should be renamed automatically too. Look at examples:

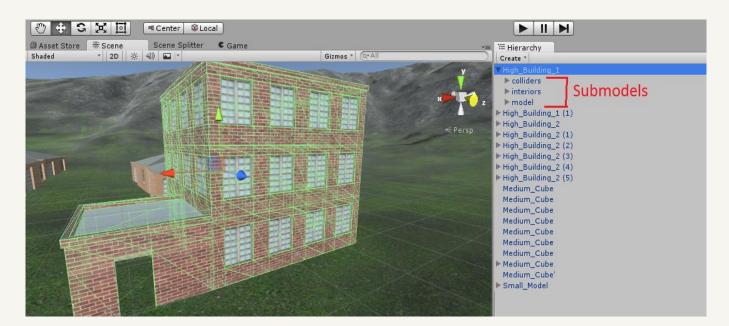

Example1. Building → Big_Objects _Building Example2. Fence → Medium Objects Fence

Example3. Flower → Small_Objects_Flower

These names will be useful in automatic segregation process. Renamed assets will save you huge amount of time and they give you ability to spreading models, without thinking what layer they belongs too. That's why prefab and objects renaming is so important. You could use this free asset to rename your objects, it is easy and fast: **Ez Files Rename** https://www.assetstore.unity3d.com/en/#!/content/31082

If you are going to stream everything at **one layer** forget about renaming, you don't need this.

3. Unpack your models from all mother folders like at this screen:

Leave your sub-models and prefabs untouched if you want to stream them as one object with its mother/parent object. If you decide to stream building details separately and in shorter distance than building general shape you should also unpack them from building. If not, you always could leave them as LOD. Probably LOD will be smarter if details are part of building prefab but that means you leave them at GC list. That means you decided to hold unnecessary objects at the scene which could be heavy in big numbers for Garbage Collector "GC".

4. Done, now it's time for splitting, layers and streaming.

6.2 Scene split and virtual grid setup

When your Objects are prepared like in <u>"6.1 Model/Object preparation"</u> section, you are ready to split them, which means we are going to put them into correct virtual grid element and layer automatically. We will continue here, the example what we started in <u>"6.1 Model/Object preparation"</u> section. Now you should follow these steps:

1. Open "Scene Splitter" window by clicking at World Streamer =>Scene Splitter

File Edit Assets GameObject Component Mobile Input Asset Store Tools World Streamer	Window Help
🖑 💠 🖸 🖾 💷 💷 Pivot 🕲 Local	
Came # Scene	-≡ Scene Splitter
Shaded * 2D 🔆 📣 🖬 * Gizmos * 🖓 All	Scene Splitter
7	Split scene by: Split x 🗹

- 2. Fill scene Splitter window:
 - Add layer
 - Check "Split X" and "Split Z" don't check "Split Y" axis, if is not so important for streaming like in Space Games is. If you don't want to remove models because of player Y position don't check "Split Y" axis. Probably for "Small_Objects", "Medium_Objects" "Split Y" axis could be useful.
 - Fill X, Z, optional Y size. Compare these with objects size and density. Don't put objects that are 100x100 units size in 10x10 virtual grid element size. Model streaming is very, very efficient, especially in build mode. At editor could be slow because of runtime batching and colliders baking. Don't worry about that, build is free from these. You could stream many buildings at once so maybe for a start try "X size" with 300 value and "Z size" also with 300 units. You can change that anytime, in few seconds you will have new setup ready to runtime test.

The thing that you should take into account is: If you want to see your building from 1500 units distance, 1500(max view distance)/300 (virtual grid element size) = 5. You will have to set streaming distance (loading range at streamer object) to $5 \rightarrow 300x5 = 1500$.

- Fill GameObject Prefix by a word that we add to recognize our big objects so by "Big_Objects". Splitter will check all objects at the scene and if any will contain "Big_Objects" at the beginning of the name it will use it in this layer.
- Fill Scene Prefix (layer name) by name which will be clear for you, it could be the same as layer name like: "Far_View" or you could add any kind of info about which world it belongs to, if you got more than 1 world. So name with this info will look like: "World_1_ Far_view ".
- Do the same operation for the rest of layers that you want to create. If you have only one layer, miss this point.

"Medium_View" for objects that contain \rightarrow "Medium_Objects" prefix

"Short_View" for objects that contais \rightarrow "Small_Objects"

You could change virtual grid element size for each layer or leave it the same.

• Important: There is no scenes/virtual grid elements limit but if you create too small virtual grid elements you will improve drawcalls count and also streaming will be slower only because of many parts to load/unload. Don't create to big virtual grid elements because you will hold in memory and garbage collector many unnecessary assets. This could affect bigger garbage collector spike. You should estimate your virtual grid size through few test. This will take only few min.

- 3. If you are sure about everything that you filled in Splitter window you could click "S" button for each layer separately or click "Split Scene" it will affect all layers. You could undo that operation by "C" button for specific layer or "Clear Scene Split" for all layers. System during split will prepare virtual grid elements from chosen assets. Virtual grid elements will become scenes in the future (next step). For more info about this section <u>"4.1 Scene Splitter"</u>
- 4. If you are sure about virtual grid elements that system made, click "Generate Scenes from virtual Grid". This is the last thing that you have to dowith your assets. System will start generating scenes from virtual grid elements. It will create scenes in specified directory or in default one. System will also create scene collection prefab called "SC+Scene Prefix". In our example we will get scene collections prefabs called: SC_World_1_Far_View or SC_Far_view; SC_World_1_Medium_View or SC_Medium_view etc...

This scene collection prefab "SC+Scene Prefix" will be stored in catalog with generated scenes. In our example WorldStreamer→SplitScenes→ "SC_World_1_Far_View" or "SC_ Far_view"; "SC_World_1_ Medium_View" or "SC_ Medium_view" etc...

5. These files (scene collections) contain all fresh info about your scenes: how many there are, how they were split, when they start and end (positions). This important scene collections prefabs called "SC+Scene Prefix" will be connected by us to streamers objects at your "Gameplay" scene. It allows you to stream this whole content in proper time and place.

6.3 Streamer setup at your game scene

After everything in <u>"6.2 Scene split and virtual grid setup</u>" section is done and we have our "SC+Scene Prefix" scene collection or collections (if we made few layers), we could start to setup our "Gameplay scene". We should open our "Gameplay" scene if we have it or create it. We are going to do all points below for each layer, some of them you could miss because they need to be done only once for first or "Major" streamer. So step by step:

- 1. Open your "Gameplay" scene, this is the place where you have player, directional light and camera
- 2. Drag and drop into your game scene hierarchy "_Streamer_Major" prefab but if you use also terrain streaming, you should use "_Streamer_Minor" prefab. Use "_Streamer_Major" if you don't going to stream terrains for this scene. If this is your second or next layer also use "_Streamer_Minor"
- 3. Check if streamer has "SceneStreamer" tag! Without this it could not work properly or simply don't run at build.
- 4. If you are going to use loading screen, drag it and drop into your game scene hierarchy "_Streamer_GUI" or "_Loading_Screen_UI" prefab. Do this only if there is no "_Streamer_GUI" or "_Loading_Screen_UI" already at the scene. This prefab contains graphical UI, Loading Screen, Teleport/Respawn and gizmo "Position" viewer for floating point fix or looping system. If this is your second or next layer you don't need to do this. We don't want to duplicate UI.
- 5. Click on "_Streamer_Major" at your hierarchy or "_Streamer_Minor" (depending on situation which was clarified above). Drag and drop your scene collection "SC+Scene Prefix", that you made in <u>"6.2 Scene split</u> and virtual grid setup" section into "Scene Collection" window. In our example it was: "SC_World_1_ Far_View" or "SC_ Far_view"; "SC_World_1_ Medium_View" or "SC_ Medium_view" etc... By this move you connected your generated scenes with streamer.

- 6. Fill streamer or streamers settings with knowledge from <u>"4.2 Streamer objects"</u> section. For this manual example we will set:
 - Loading range to X= 5, Y = 0, Z = 5 for buildings that must be visible from 1500units and each virtual grid element(scene) is 300x300 units 300x5=1500units
 - Use Loading Range Min = false
 - Deloading Range X= 5, Y = 0, Z = 5
 - Destroy Tile delay = 1 second
 - Position check time = 0.1 seconds
 - Max Parallel Scene Loading = 1
 - Looping = false
 - Scene Loading Wait frames = 1 or 2 frames

Summing up that means we will load area 5x5 of virtual grid elements(scenes) where each virtual grid element is 300x300 and unload every virtual grid element that is further than this. We will check our position every 0.1 second. We will load max 1 virtual grid element during one frame and we left 1-2 frame to finish asynchronously stream operation, after virtual grid element was loaded and before we load next one.

- We fill "Player" window by drag and drop our player from scene hierarchy into "Player" window. Our system will follow that player and load terrain tiles if they will be close enough.
- 7. Now we will fill our UI, of course only if we want to use loading screens.
 - We click at "_Loading_Screen_UI" object at "Streamer_GUI" in scene hierarchy and we write Size = 1 or more (if we have more streamers) in Streamer value. You could find this value in "UI Loading Streamer Script".
 - Now we need to drag and drop our "_Streamer_Major" from scene hierarchy as element 0 in "UI Loading Streamer Script". If your used streamer prefab is "_Streamer_Minor" it should be at element 1 or further. Please drag and drop into this window rest of the streamers if you want to use them in Loading Screen. If you decided to not affect Loading screen by small details "Small_Objects" don't add them there.
- 8. Now we click at "_Streamer_Major" and at every streamer prefab "_Streamer_Minor" at the scene and if you didn't added scenes from scene collections to the build setting, you should see a warning with button. Click on it and system will automatically add missing scenes or refresh them in build settings. Each time you change number and size of virtual grid elements you have to clicking that button!

Looping	•	
Add scenes from scene collection to b	ild settings.	
	Add scenes to build settings	

9. Click play and it works!

Important!

Now you could easily split/unsplit/add new objects/remove content/move content and you could refresh layer with objects and streamed world in few seconds by click split and generate again at your work scene or by our "local area updater". System will refresh your scenes and "_Streamer_Minor/Major" at your game scene. You only need to refreshed them by clicking add to build settings button. That mean you could easily test many configurations!

7. Streaming by colliders

This is new function in World Streamer, it's available only for Unity 5.3+ (Multi-Scene-Editing) versions. Collider streaming is useful to load/unload/cull interiors/rooms/floors or you could simply just load something only when player/object hit the collider. This function could save you a lot of cpu/gpu/ram/vram usage, you are able to fill whole town by interiors and load them only when player hit the doors or nearby area. It's really easy and fast in use.

7.1 Object preparation, split and scene generation

It's very simple. Let's do it step by step.

- Create empty game object near objects that you want to stream by collider. Let's name it "Collider_Stream_Interior_1"
- 2. Attach collider to this game object and check "is trigger".
- 3. Adjust collider size to the area in which streamed objects should be loaded and stay in memory
- 4. Move objects that you want to stream into "Collider_Stream_Interior _1" object, let these objects become their children in scene hierarchy
- 5. Attach ColliderScene object to our "_Interior _1".
- 6. After all these steps situation should look like this:

🖑 💠 🖸	X I	🕫 Center 🛛 🕸 Local

Medium_Cub	be (4)											
Medium_Cub	be (5)											

- 7. Open Scene Splitter window
- 8. Hit "Generate scenes from colliders only" button.
- 9. Generation process, just generated scene "Collider_Stream_Interior _1" scene and prefab with collider "Collider_Stream_Interior _1_stream". You could find them in WorldStreamer catalog → SplitScenes → ColliderScenes. Prefab contains connection to the generated scene and it holds original object position. If

you move this prefab from project window to hierarchy at any other scene, objects will be in the same place as in scene where they have been generated. Of course you could change prefab and spawning position.

Important!!! Our system gives you ability to hide your objects streamed by collider in scenes that are streamed by streamer from scene collections (virtual grids). This looks like small matrioshka, scene that stream scenes etc... Simply put them in any layer, during generation process system will recognize that it found objects that are streamed by colliders. It will create scenes for this objects and put in correct places. The only thing that you have to do is to add them to build settings by SceneSplitter→BuildSettings→"Add scenes to build settings" button. After you generate scenes this window should be automatically filled with proper objects. Another advantage of this construction is, if layer in which you left your collider streamed objects will properly follow world and player. If you only use this construction in your project, you don't have to pass through <u>"7.2 Collider streamer setup at you game scene"</u> section. The only thing to have to do from this section is: Drag and drop from project into "Gameplay" scene hierarchy "_Collider_Streamer_Manager". This prefab must have "ColliderStreamerManager" tag. Check it! Fill it with player object from your scene hierarchy.

7.2 Collider streamer setup at your game scene

It is much easier than generating.

- 1. Open "Gameplay" scene
- 2. Drag and drop from project into scene hierarchy "_Collider_Streamer_Manager". This prefab must have "ColliderStreamerManager" tag. Check it! Fill it with player object from your scene hierarchy.
- 3. Simply move generated prefab "Collider_Stream_Interior _1_stream" from project window into your scene hierarchy window.
- 4. Hit add to build settings button. If you forget about this, scene will not load.

Looping	
Add scenes from scene collection to build settings.	
	Add scenes to build settings

- 5. Decide if only player during hit should initiate streaming by checking "Player Only Activate" or not.
- 6. Set up unload Timer. After this time scene will be unloaded, but this will happen only when streaming initiator leaves collider area.
- 7. Click PLAY and Move your player/object and hit collider. Objects will become loaded.

8. Multiple layer streaming - why you need this.

We put a lot of attention into layers at section <u>"6.Model/Objects Streaming"</u> and <u>"5. Terrain Streaming"</u>. Everything is about performance.

The idea is to hold as low amount of objects at your game, as it's possible. If you left low amount of objects at the scene some scripts could work faster. When you call garbage collector, its spike will be reduced to value that you could skip. If you want to remove objects from memory/CPU you have to call GC (garbage collector) from time to time. We could look at this from second side. If your GC is still too heavy, with layers you will not have to call it so often.

Layers give you ability to hold this assets that are really necessary for you at current moment. Small objects will be removed from your memory and CPU (also GC list), if they are far enough. We give you ability to hold big shapes like buildings, terrains in far distance, and enjoy the big amount of details that will eat your resources only at short distance.

Layers with ring streaming give you ability to replace detailed and heavy unity terrains by low poly meshes. Unity LODs system don't support this construction. We will say more, in this construction you don't hold/load LOD0 at/to memory if it's not necessary. This dosen't have to be terrain, what do you think about replacing particles by static billboard mesh at far distance? With unity LODs even if you switch to billboard, particles will still eat your CPU. With many particle sources you could save a lot by our ring streaming.

Layers could be useful to separate following objects: Lights, FX, Models, AI. While they are separated, multiple developers with different specializations could work at the same area, without interfering with each other.

Summing up, layers give you ability to optimize your game a lot and hold very detailed world without any performance issues. Users have performance increase by more than 200-300%. As layer streaming range is a dynamic value, player could have this range adjustable at setting

9. Local Area updater

Local Area updater is a tool that gives you ability to refresh/work/rise your split world without loading everything again. This system require unity 5.3+ version. Local area updater could be useful when few developers work at the same area, but on different layers or they are working at the same layers at the same world but at its different places/regions. By layers word we mean - AI, FX, Models, Light, Big models, small models, terrains.

9.1 Local Area updater options

- Open empty scene and save it. You could call it "Local Area Updater Scene"
- Open Local Area Updater window. World Streamer → Local Area Updater

Edit Assets GameObje	ect Component	World Streamer Mobile Input	Window	Help		
) + S X II	■ Center 🕻	Local Area Updater				
Asset Store # Scene	Scene Splitte	Scene splitter	ect			
Local Area						□ × *≡
Settings			V			
▼ Scene collections:						
size	0					
Loading distance	0					
Tiles		U	nits	\checkmark		
Loading Center	X 0	Y 0			Z 0	
Show loading center	\checkmark				Show center	
		Load Scenes from Collectio				
		Load All Scenes fr	om Collec	tions		
Update						
		Unsplit S	cenes			
		Split Sci	enes			
		Remove empty o	rid eleme	nts		
		Save loaded	Scenes			
		Unload loade				
L		Delete empt	y Scenes			

- Scene collections is a place where you can add your multiple or one scene collection "SC+Prefix" prefabs. From this "scene collections", system will load split scenes (virtual grid elements) for you. Remember about layer correct order if you use multiple layers. When you use layer with empty prefix, system could put your models to wrong scenes when you hit "Split Scenes"! Scene collection with empty prefix should be last one on the list.
- Loading distance is a range of loaded world. It could be in virtual grid elements (scenes) or unity units you could chose by checkbox below. When unity units option is checked, unity units distance will be recalculated into virtual grid elements. Unity units are useful when layers which we want to load have different virtual grid elements size. As an example we want to load terrain, models and fx that belongs to this terrain area. Terrain is at different layer than models and fx and it has different virtual grid elements size than them. In this case we should use Unit size loading distance.
- Loading center is the XYZ position in around which local area updater will load models/objects, in range that you specified above. Soon we will add also streaming that follow unity camera in editor.

- Load scenes from collections around Center point will immediately load your scenes, from chosen scene collections, around the point you chose and in range that you setup.
- Load all scenes from collections will immediately load all scenes that are connected to chosen scene collections.
- **Unsplit scenes** button it's useful when you want to create your big scene from split scenes(virtual grid elements). You simply need to load all scenes from collections then click "unsplit" and you have your big scene with all models in one place again. By this button you could merge your layers, because you simply remove their virtual grid elements membership.
- Split scenes button will put new added or moved models to correct scenes, layers and virtual grid elements.
- Save loaded scenes button will immediately create new or actualize old scenes with changes that you made in virtual grid elements. It will actualize your scenes **but** you have to click "Split scenes" button before you click "save loaded scenes". It will <u>show you bugged unity window, simply click ok or enter</u>. This window contain list of scenes that you updated. If list is too big unity window is bugged, we have no access to it, to fix that. Just don't care about this and click enter.
- Unload loaded scenes will remove your loaded scenes and you will get back to clean empty scene.
- **Remove empty virtual grid elements** by this button you could remove empty scenes from scene collections. This will avoid empty scene loading during gameplay.
- **Delete empty scenes** will delete empty scenes from your project, sometimes it's useful to hold them. As an example if you are going to put new models in this area, system will not have to create new scenes again. So you could hold empty scenes and clean them at the end of work.

9.2 Workplace setup, virtual grids loading, world refreshing

1. Open empty scene and save it as "Local Area Updater Scene".

2.

pen Local Ar	ea Update	r window					
Edit Assets GameOb	ject Component	World Streamer Mobile Input	Window	Help			
) + S M 🗉	⊂ Center 🕻	Local Area Updater					
Asset Store #Scene	Scene Splitte	Scene splitter	ect

		Remove empty		ante			
		Kennove empty	gria elerne	ints			
		Save loade	ed Scenes				
		Unload load	ed Scenes				
		Delete emp	ty Scenes				

- 3. Set number of layers that you want to load. Scene collections \rightarrow click on the arrow \rightarrow type number/size
- 4. Drag and drop into list your "SC+Prefix" scene collection prefabs. Remember about layer/scene collections correct order if you use multiple layers. When you use scene collection with layer that contains empty prefix, system could put your models to wrong scenes when you hit "split scenes"! Scene collection with empty prefix should be last one on the list.
- 5. Set size of the area that you want to load in virtual grid elements (scenes) or in unity units.
- 6. Set point from which you want to load your area "Loading Center"
- 7. Click "Load Scenes from Collections around Center Point", system will immediately load virtual grid elements (scenes) from chosen scene collection in specified range.
- 8. Make changes that you want to do for example: add objects, remove, rise your world by new regions, move objects.
- 9. Hit "Split scenes" button, it will sort, move new and old content into correct layers and virtual grid elements. In this place if you use layer with empty prefix and it is on the top of the scene collection list, everything will be moved only to this layer and nothing will be left for the rest of the list.
- 10. Click "Save loaded Scenes", this will save your changes and refresh/actualize scene collection "SC+Prefix" prefabs.
- 11. "Unload loaded scenes" this will remove all content and clean your "Local Area Updater Scene".
- 12. If system had to create new scenes, you should add them to build setting. You could do this by our tool scene splitter or at "Gameplay" scene by clicking at each streamer object and clicking at error button "Add to build settings". Button will show up only if there will be changes in amount of scenes.

10. AI and navmesh solutions

When you are streaming your world there are always problems with AI and navigation mesh. There are few ways to handle this problem. Most difficult to handle could be floating point fix system with looping. Anyway don't worry as we rely on our and users experience, everything could be done and will not cost a lot of work.

10.1 Custom navmesh solutions

This solution is the easiest. There are few AI solutions that don't need navmesh or they give you ability to save it in parts and load.

APEX solution, don't require navmesh it even react geometry changes. Fast and very advanced, it fits most • projects.

https://www.assetstore.unity3d.com/en/#!/search/page=1/sortby=popularity/query=publisher:6827

- A* Pathfinding gives you ability to bake navmesh in parts, load and everything will work fine. You could load • this navmesh as separate layer and virtual grid element from time to time. When navmesh is saved as game object, you could move it. That mean it could be used with floating point fix and looping system. https://www.assetstore.unity3d.com/en/#!/content/1876
- If you have tried more solutions and they work well for you give us a sign and contact us, we would love to include them here. Probably most solutions that give you ability to save navmesh in parts and connect parts at runtime will work fine. All solutions that do not require navmesh for pathfinding will work fine too, assetstore is full of them.

10.2 Unity navmesh

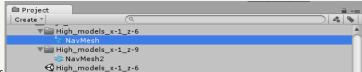

With streamed world you could use unity navmesh. It could be loaded and removed with scenes, but you cannot move it. That mean it is not going to work with floating point fix and looping systems. In all other cases it's ok. As we know unity is working at navmesh which will be connected to objects. With that architecture, when they finish it, even floating point fix and looping system will work fine.

Here are the options that you could use at the moment with unity navmesh:

- Navmesh in one part: You also could always hold navmesh for whole world in gameplay scene. Navmesh is • an object that you could move between unity catalogues. You could bake it at "Work" scene with all objects, and after you finish baking, you could copy it and paste into "Gameplay" scene catalog. If you don't have actual work scene you could rebuild it at empty saved scene, by our local area updater tool. This tool loads all scenes from scene collections that you decide to use. For more info check "9. Local area updater" section.
- Navmesh in many parts: Load specified area by local area updater. For more info check "9. Local area updater" section. When you load your area you could bake navmesh for it. Then you have to copy and paste navmesh object, into scene that it should belong to. This could be scene that will be loaded by collider (easiest way) or any other scene streamed by streamers. You could even prepare fake scenes with huge virtual grid elements (their size is equal to navmesh area) with only one empty game object. This game object will be only useful to create and stream scenes. After navmesh baking you will need to fill scene

catalogues with proper navmesh part.

Support: Email contact: Naturemanufacture@gmail.com

10.3 AI spawn, single and multiplayer versus floating point fix and looping

It's pretty simple to handle this. Here is pack of details that will help you.

- Al spawn. While player is moving and we use floating fix system with looping or not, our player position is reseted from time to time. World Mover script holds position differences between local player position (after reset) and real player position. Player position (XYZ) Current Move (XYZ) = Player real position (without reseting). This values are useful for spawners to correct spawn position to actual player position. If it's single player you could move spawners with player by attaching and filling "object to move" script. Check "4.5 Floating Point Fix system" section.
- Al pursuit. While player is moving and we use floating fix system with looping or not, our player position is reseted from time to time. To avoid dropping our Al followers:
 - Single player: you have to attach "object to move" script to each NPC object and fill it on start by actual "_World_Mover" object at your scene. For more info check: <u>"4.5 Floating Point Fix system"</u> section.
 - Multiplayer: simply correct rpc/message with position by "Current Move" value from client World Mover script. For more info check: <u>"4.5 Floating Point Fix system"</u> section.

11. Version changes

Version 1.1 changes:

- When you rebuild scenes, world streamer don't miss Scene collection prefab anymore.

- When you type wrong GameObject Prefix in Scene Splitter you will get info: No object to split.

- When you made mistake with "Scene create folder" you will get info, about that the folder doesn't exist, crash problem have been removed.

- Scene collection object now have name from scene objects "Scene Prefix".

- During scenes generating, when scene prefix will be typed wrong you will get an info - No objects to build scenes.

version 1.2 changes:

- Float point fix
- Multiple streamers support
- Reduced memory usage during scenes creating process
- Improve scenes creating speed

version 1.3 changes:

- Improve scenes creating speed
- Multiple sorting process for few layers at once
- Multiple steamers automatic scene creating for multiple layers and streamers
- Cancel creating scene process
- Warning if you forgot about: streamer tag or deloading range is shorter than loading, thx for feedback!
- Save options for sorting process
- Streaming layers manager in scene splitter
- Documentation update
- Index out of range fix, it could show in very specific situations
- Manual update with more tips and details, thx for feedback!
- Support: Email contact: Naturemanufacture@gmail.com Skype contact: dahrrrr Manual author: Bartłomiej Galas Facebook: https://www.facebook.com/NatureManufacture-559454417506747/?fref=ts

version 1.4 changes:

- Automatic resizing looped world system,
- Different stream range in selected axis
- Gizmos with information about future sectors
- Scrollbar in scene splitter window
- Webplayer support
- Generate scenes for separated layer "G" button
- Compatibility with terrain stitcher and multiple terrain brush

version 1.5 changes:

- Scene creating is 20 times faster it requires unity 5.3 +
- Added new loading/deloading it requires unity 5.3+
- Local area updater tool [beta] it requires unity 5.3+
- Additional support for huge teams that work on one world
- Additional support for huge world

version 1.7 changes:

- Sectors were renamed to virtual grid elements.

- Added new necessary tags You must add the following tags to the project: SceneStreamer, WorldMover, ColliderStreamerManager.

✓ SceneStreamer

The SceneStreamer tag must be assigned to any GameObject that uses a Streamer.cs script. The _Streamer_Major and _Streamer_Minor prefabs must have the SceneStreamer tag.

✓ WorldMover

The WorldMover tag must be assigned to any GameObject that uses a WorldMover.cs Script. The _World_Mover prefab must have the WorldMover tag.

✓ ColliderStreamerManager

The ColliderStreamerManager tag must be assigned to any GameObject that uses a ColliderStreamerManager.cs script. The _Collider_Streamer_Manager prefab must have the ColliderStreamerManager tag.

- Bug fixes with looped world which start from "-" positions.
- Bug fixes with looped non-square world
- Bug fixes with local area updater (non default scene directory)
- Bug fixes with scene splitter (non default scene directory)

- New gizmos for sectors (now we call them virtual grid elements). You will be able to visualize how far you stream every layer and compare them. They are available at work and gameplay scene.

- System speed up
- Changes in UI to more intuitive, we removed some windows and we make system more automatic

- Collider streaming, it requires unity 5.3+. You will be able to stream virtual grid elements that only show up when player or other object hit collider. Useful for building interiors! Collider could be looped, it will be also compatible with floating point fix system. With this system you could avoid loading big group of invisible models.

- Collider streaming could be used in streamed scene so you could build matrioshka constructions from streamed objects. We mean object that stream object.

- Ring streaming - by that you are able to load objects in specific range and then replace them when you are close or far enought. It could be usefull as LODs for far view terrains. At close distances you will have terrain at far distances you could load low quality mesh. You also could use it to replacing objects/models in different distances.

- New big manual doc.
- More world examples, advanced and simple.
- World Streamer components become prefabs.

version 1.7.2 changes:

- faster GC (Garbage Collector) solution
- hide few debug values
- terrain culling system script. With it you probably will save 90-10% of terrain cpu usage/gpu. (Unity 5.3+)
- manual changes
- more info about real time generated data and world streamer workflow (concept image)
- minor bug fixing, they do not affect system workflow

Big thanks for feedback! We are always open, we would love to help you to make cool games!

12. TIPS, additional info, performance problems and solutions

- If texture streaming is slow/generates spikes please called "GFX wait for present" adjust "Async Upload Time Slice" and "Async Upload Buffer Size" in Quality settings.
- You can check performance only in development build with auto-connect profiler option. Access to memory in unity editor is very slow and generates many CPU spikes that will not show up at game build. To reduce spikes at editor you could turn off static batching for a while.
- Terrains LODs are automatically synchronized and blended if there is our "terrain neighbour" script. It must be at your not destroyable object in gameplay scene. You could attach it into "_Streamer_Major" If you use floating point system, you have to connect it with "world mover" script at your scene hierarchy. Simply drag and drop world mover object or object with that script from hierarchy into "terrain neighbour" script to window called "World Mover". If you will put more than one terrain neighbour script at the scene you could get **spike from Split.Scene.manager.Start**. You need only one neighbour script!
- If you want to remove textures from memory at your games, use amplify, granite other texture streaming system. Check <u>14. Third party assets that might be helpful</u> section. This will allow you to use unlimited resolution of textures without memory grow. Streamer will work extremely faster, because it will load only colliders, meshes, terrains. Textures will be streamed from block by other outside system.
- REMEMBER to check your static objects as static! It will reduce CPU use during scene streaming process (build only). If you use floating point system fix, you have to batch/bake object by using custom tool.
- REMEMBER to check "Prebake Collision Meshes" box at player settings, to stream colliders much faster! This option will make your game build time much longer! Best option is to use it at final builds.
- We advise you to check "optimize mesh data" box in player settings, this will reduce game build size and stream time, but it will extremely lengthen the build time! So check it only on final build or when you have much time.
- Shader.set.Parser spike (in older unity versions) during your streaming: If you don't have speedtree objects at game starting location you have to put empty boxes with empty speedtree shaders: bark, leaves, billboard. Normally unity should initialize these shaders if they are added to "GraphicsSettings" in "Always

Included Shaders" but this is a temporary unity bug. There also could be problems with other specific shaders at unity!

- Culling per patch spike on CPU while terrain loading. You probably have to much trees and grass at your loaded scene. This is unity terrain bug. You could reduce that if you change detail resolution per patch to 16. We don't know why 16 but it work faster than 8 and 32 or any other value. When unity load terrain it refresh all trees and grass objects at existing already loaded scenes too. It's stupid but haven't been fixed yet by unity. You could also reduce it, by hiding terrains that are not in your current view by our "Terraincullingsystem" script. Simply drag and drop it on terrain object/prefab and set max visibility distance for this terrain (Unity 5.3+). Check <u>"5.5 Huge amount of details at unity terrain and performance solutions."</u> section for better solutions. You could cure your project from this problem in many ways.
- Every error or warning at your scenes will slow down stream system. Remember to clean your scenes from bugs and mistakes.
- Use as simple colliders for your objects as possible! If colliders are baked (player settings) they are loading much, much faster. Anyway simple colliders are healthier for your project.
- If your scene is to heavy, cut it into smaller parts and load with bigger range. You will load many small parts and this way guarantee better performance. Good way is also to load terrain separately by second world streamer prefab. The clue is do not load everything at once!
- Remember that terrain detail resolution, control texture resolution, base texture resolution, heightmap resolution also affect streaming performance so adjust it wise. If you don't need so much details, cut unused data by setting lower value.
- If Garbage Collector "GC" function spikes too heavy (spikes), you probably have to much objects at your scene. You probably have spike at GC.Mark.Dependencies function which is related to amount of game objects at the scene. You could reduce it by layer adjustment. You should hold in scene only things that you actually need. This could be also your/unity scripts memory leak bug. You could change density of GC by yourself in our scripts or remove it and call from time to time by your own script. Anyway remember if you got GC spikes, you made something wrong. It could be also Unity bug, sometimes unity function also have memory leaks.
- With ring streaming you could replace particles by static billboard mesh at far distance. With unity LODs even if you switch to billboard, particles will still eat your CPU. With many particle sources you could save a lot by our ring streaming.
- With ring streaming you could replace heavy unity terrains by low poly mesh at far distance. This could save hundreds MB of memory, avoid CPU spikes and remove static CPU usage that unity terrain refreshing generates all the time..

13. Our other assets that might be helpful

- Multiple Terrain Brush tool that gives you ability to work on multiple terrains as they were one big terrain. It also could fix edges between terrains or could be handful to loop your terrains. <u>https://www.assetstore.unity3d.com/en/#!/content/44037</u>
- **Terrain Stitcher** this tool could massively stitch/fix/blend/loop your terrains. Only one button and holes disappear. It has many different stitching variants, very advanced math functions. It is also useful to loop your terrains quickly. <u>https://www.assetstore.unity3d.com/en/#!/content/42671</u>
- **PBR Graveyard Pack** this pack contains huge amount of PBR sculpted cemetery and nature assets that are high-quality models with LODs. Last LODs for big models are Billboard. Pack contains 128 prefabs, 225 textures, 152 models, 2 soundtracks

https://www.assetstore.unity3d.com/en/#!/content/58915

- Landscape Ground Pack pack contains 105, seamless high quality PBR ground textures. https://www.assetstore.unity3d.com/en/#!/content/63023
- Winter Ground Pack pack of 45 winter textures high quality PBR ground textures.. https://www.assetstore.unity3d.com/en/#!/content/54301
- **Mountain Tree Pack** is consisting of 7 high-quality spruce trees, grass texture and few ground textures. <u>https://www.assetstore.unity3d.com/en/#!/content/26713</u>
- **Realistic Tree Pack** is consisting of 44 high-quality trees, with bark and leaves. There are 8 different tree types with individual types of leaves and barks, which could also be combined in various ways giving in total 64 combinations of different trees!

https://www.assetstore.unity3d.com/en/#!/content/19907

14. Third party assets that might be helpful

Amplify Texture 2 - solution will remove your textures from memory and stream them from one big block. It will stream only necessary textures that are currently visible at your screen. This reduces your memory usage a lot.

http://amplify.pt/unity/amplify-texture-2/

Granite - solution will remove your textures from memory and stream them from one big block. It will stream only necessary parts of textures that are currently visible at your screen. This reduces your memory usage a lot.

http://graphinesoftware.com/products/granite-for-unity

APEX - solution, don't require navmesh it even react geometry changes. Fast and very advanced, it fits most projects.

https://www.assetstore.unity3d.com/en/#!/search/page=1/sortby=popularity/query=publisher:6827

- Runtime Mesh Batcher is a custom batching solution. https://www.assetstore.unity3d.com/en/#!/content/26200
- **uConstruct** is building system that is compatible with World Streamer. https://www.assetstore.unity3d.com/en/#!/content/51881
- A* Pathfinding gives you ability to bake navmesh in parts, load and everything works fine. You could load this navmesh as separated layer from time to time. As navmesh is saved as object, you could move it. That mean it could be used with floating point fix and looping system. https://www.assetstore.unity3d.com/en/#!/content/1876
- **uNature** custom grass system that removes problem with detail density at your unity terrains •
- Trees Manager System custom interactive tree system ٠ https://www.assetstore.unity3d.com/en/#!/content/43129
- World Creator very advanced terrain generator, it support terrain tiling. ٠ https://www.assetstore.unity3d.com/en/#!/content/55073
- Gaia helpful terrain generator, it supports tiling also it have stamps for our 3d/2d assets. ٠ https://www.assetstore.unity3d.com/en/#!/content/42618
- Terrain Composer cool terrain generator, it also has its own terrain streaming but you only could stream objects generated by system. https://www.assetstore.unity3d.com/en/#!/content/65563
- Curved World could curve your world, if you use looping system and this asset you could get planet • imitation effect.

https://www.assetstore.unity3d.com/en/#!/content/26165

- Ez Files Rename easy and fast tool which will rename your objects at project and hierarchy. It's useful to • rename your assets to layer and split purposes. https://www.assetstore.unity3d.com/en/#!/content/31082
